The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—Before admission to this examination the candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry, Physics, and Practical Chemistry. The examination consists of these subjects and is identical with Part I. of the First Examination of the Examining Board in England. II. The First Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during a period of not less than three years in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction (which may be taken prior to registration as a dental student) of a competent Practitioner or under the direction of the Superintendent of the Mechanical Department of a recognised Dental Hospital. In the case of qualified surgeons evidence of a period of not less than two, instead of three, years of such instruction will be sufficient. 2. Of registration as a dental student by the General Medical Council. 3. Of having attended at a recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy; (*c*) a course of Lectures on Dental Mechanics; and (*d*) a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns. Candidates may present themselves for the First Professional Examination after the completion of six months' attendance at a recognised Dental Hospital and School. The Examination consists of Mechanical Dentistry and Dental Metallurgy; the examination in Dental Metallurgy will be by written paper. III. The Second Professional Examination.—The Candidate must produce the following certificates: 1. Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student. 2. Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology; (*b*) a separate course of Dental Histology, including the preparation of microscopical sections; (*c*) a course of Dental Surgery; (*d*) a separate course of Practical Dental Surgery; and (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery. 3. Of having attended at a recognised dental hospital or in the dental department of a recogised general hospital the practice of Dental Surgery during two years. 4. Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy, (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology, (*d*) a course of lectures on Surgery, and (*e*) a course of lectures on Medicine. 5. Of having performed Dissections at a recognised medical school during not less than twelve months. 6. Of having attended at a recognised hospital the practice of Surgery and Clinical Lectures on Surgery during two winter sessions. 7. Of being twenty-one years of age. The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers. Candidates may present themselves for the Second Professional Examination after the completion of four years' professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination. The Second Professional Examination consists of General Anatomy and Physiology, General Surgery and Pathology, Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. The written examination comprises General Anatomy and Physiology, General Pathology and Surgery, Dental Anatomy and Physiology, and Dental Pathology and Surgery. At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries, and may be required to prepare and fill cavities with gold or plastic filling or material, or to do any other operation in Dental Surgery (candidates must provide their own instruments); (*b*) on the Mechanical and Surgical Treatment of the various irregularities of Children's Teeth. There is also an Oral Examination. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination of the Royal College of Surgeons of Edinburgh, of the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or of any University in the United Kingdom. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned. The fee for the diploma is 20 guineas and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 2 guineas; Second Professional examination, 5 guineas; the balance to be paid on the completion of the Examinations. The Preliminary Science Examination is held in January, March or April, July, and October in each year. The First and Second Professional Examinations are held in May and November in each year. Candidates must give twenty-one clear days' notice of their intention to present themselves for examination.

Royal College of Surgeons, Edinburgh.—For the Licence in Dental Surgery all candidates must pass a Preliminary Examination in General Knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council. A copy of regulations, giving a list of Preliminary Examinations recognised for obtaining this Licence, as well as of the subjects of the Professional Examinations, may be obtained from Mr. James Robertson, Clerk to the Royal College of Surgeons, at 48, George-square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd, 1878, are exempt from the Preliminary Examinations. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates who have commenced their studies *after* Oct. 1st, 1890, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, one course of six months; Practical Chemistry, one course of three months; Physiology, one course of six months; Materia Medica, one course of three months; Surgery, one course of six months; Medicine, one course of six months; and attendance on the practice of a recognised general hospital, with Clinical Instruction, twelve months. (Candidates who commenced study in accordance with the regulations in force before July, 1895, shall not be required to attend more than six months' hospital work.) These courses must have been attended at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology (Human and Comparative) (not less than 24 lectures), Dental Surgery and Pathology (not less than 20 lectures), Dental Mechanics (not less than 12 lectures)—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either

Digitized by Google

for the First Dental Examination or for the First and Second Examinations for the Triple Qualification, as they may select, and subject to the existing regulations for each qualification. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Chemistry and Physiology. The fee is £4 4*s*. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is twenty-one years of age, and must pay a fee of £6 6*s*. The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics with Dental Metallurgy. Unsuccessful candidates will be repaid £2 2*s*. in the First and £3 3*s*. in the Second Examinations. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10*s*. payable for the dental diploma, of which £3 3*s*. will be returned in case of rejection. The fee payable by candidates who begin study after Oct. 1st, 1896, shall be £15 15*s*.

Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. There is a practical examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital.

Royal College of Surgeons in Ireland.—All information concerning the licence in Dentistry may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September. Primary Dental Examination.—Fee £10 10*s*.; for re-examination, if rejected, £5 5*s*. Every candidate[2] is required, before admission to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections, two courses of six months each; Lectures on Chemistry, six months; Lectures on Physiology, including Dental Physiology, six months; Practical Histology; and Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical Instruction at a recognised general hospital for one year. The subjects of this examination are: (1) Physics;[3] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I. or students who have passed Primary Dental or Third Professional Examination of the College, £10 10*s*.; re-examination, £5 5*s*. Fees for Final Examination of all other candidates, £26 5*s*.; re-examination, £10 10*s*. Extra fee for Special Examination, £5 5*s*. Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following courses of lectures recognised by the College: Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a dental hospital recognised by the College or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination: Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the Workshop). Examinations for the Licence in Dentistry *sine curriculo:* The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

TEACHING INSTITUTIONS.

ENGLAND.

Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school was founded to provide the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. There is a good mechanical laboratory, and opportunity is afforded students of gaining practical experience in taking models and fitting dentures into the mouth. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The eight house surgeoncies are held for one year each, and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. A scholarship of the value of £20 has been founded by Sir Edwin Saunders and will be awarded to the student who has obtained the highest aggregate number of marks in the five class examinations—viz., the four Lecturers' Prizes, the Operating Prize—and in additional special *viva voce* examinations in Practical Dentistry. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. A prize of the value of 5 guineas is given by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. The conditions under which this prize is to be competed for are the same as those for the Saunders Scholarship, with this

[2] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[3] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

exception, that the papers are to be written in the hospital during the summer session. Consulting Physician: Sir Richard Douglas Powell, Bart., M.D. Consulting Surgeon: Mr. Christopher Heath, F.R.C.S. Consulting Dental Surgeons: Mr. T. Arnold Rogers, M.R.C.S., L.D.S., and Mr. Smith Turner, M.R.C.S., L.D.S. Dental Surgeons: Leonard Matheson, L.D.S.; E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A.; W. B. Paterson, F.R.C.S., L.D.S.; W. H. Woodruff, L.D.S.; A. Clayton Woodhouse, M.R.C.S., L.D.S.; and J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S. Assistant Dental Surgeons: C. F. Rilot, L.R.C.P., M.R.C.S. L.D.S.; H. Baldwin, M.R.C.S., L.D.S.; H. Lloyd Williams, M.R.C.S., L.D.S.; W. H. Dolamore, L.R.C.P., M.R.C.S., L.D.S.; Percy Smith, L.R.C.P., M.R.C.S., L.D.S.; G. Hern, L.R.C.P., M.R.C.S., L.D.S.; J. G. Turner, L.R.C.P., F.R.C.S., L.D.S.; Russell Barrett, L.R.C.P., M.R.C.S., L.D.S.; Ashley Densham, L.R.C.P., M.R.C.S., L.D.S.; N. G. Bennett, M.A., M.B., L.D.S.; and D. P. Gabell, L.R.C.P., M.R.C.S., L.D.S. Anæsthetists: Dudley W. Buxton, M.D., B.S. Lond., M.R.C.P. Lond.; Frederic W. Hewitt, B.A., M.D. Cantab.; Carter Braine, F.R.C.S.; Henry Davis, M.R.C.S., L.S.A.; George Rowell, F.R.C.S.; and E. A. Bridger, M.D. Assistant Anæsthetists: R. Turle Bakewell, M.B. Lond., L.R.C.P., M.R.C.S.; Harvey Hilliard, L.R.C.P., M.R.C.S.; R. J. Probyn-Williams, M.D. Durh.; H. Bellamy Gardner, L.R.C.P., M.R.C.S.; George Flux, M.D. Brux. Demonstrators: H. Austin, M.D. Lond., L.D.S.; R. Herschell, L.D.S.; H. W. Trewby, L.R.C.P., M.R.C.S.; and J. R. Freeman, L.D.S. Medical Tutor: W. S. Nowell, M.A. Oxon., L.D.S. Curator of Mechanical Laboratory: W. E. Fletcher. Lecturers.—Dental Anatomy and Physiology (Human and Comparative): Charles Tomes, F.R.S., M.A. Oxon., F.R.C.S., L.D.S., on Wednesdays and Saturdays, at 8 A.M. (Summer). Dental Surgery and Pathology: Storer Bennett, L.R.C.P., F.R.C.S., L.D.S., on Tuesdays and Fridays, at 8 A.M. (Summer). Mechanical Dentistry: E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A., on Wednesdays, at 5 P.M. (Winter). Metallurgy in its Application to Dental Purposes: Dr. Forster Morley, M.A., F.I.C., F.C.S., on Thursdays, at 5 P.M. (Winter). During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. Fee for two years' hospital practice required by the curriculum, including lectures, £50 in one payment, or 50 guineas in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £55. Both hospitals can be attended simultaneously. The Dean, Mr. Morton Smale, attends at the hospital every Wednesday morning from 10 to 12, or he can be seen at other times by appointment. Letters to be addressed—40, Leicester-square, "to be forwarded."

National Dental Hospital and College.—Winter Session, 1898-99, commences on Oct. 3rd at the new building at the corner of Great Portland and Devonshire-streets, W.—Consulting Physician: Sir W. H. Broadbent. Consulting Surgeon: Mr. Christopher Heath. Consulting Dental Surgeon: Sir Edwin Saunders. Visiting Physician: Dr. James Maughan. Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H. Weiss, Mr. A. Smith, Mr. M. Davis, Mr. T. G. Read, Mr. Rushton, and Mr. C. W. Glassington. Assistant Dental Surgeons: Mr. W. Weiss, Mr. E. Beverley, Mr. S. F. Rose, Mr. A. E. Relph, Mr. W. H. Wheatley, and Mr. H. J. Relph. Anæsthetists: Dr. Flux, Mr. C. E. A. Macleod, Mr. C. J. Ogle, Mr. G. E. Norton, Dr. J. Maughan, and Dr. Harold Low. Lecturers (winter), Dental Anatomy and Physiology: Dr. J. W. Pare, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Practical Dental Surgery: Dr. George Cunningham, Mondays, 6.30 P.M., in October, November, and December. Dental Materia Medica and Therapeutics: Mr. C. W. Glassington, Tuesdays, 6 P.M., in October, November, and December. Dental Metallurgy: Dr. A. B. Griffiths, Tuesdays, 5.45 P.M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Wednesdays, 6 P.M., in January, February, and March. Summer—Dental Surgery and Pathology, Mr. Hopewell Smith, Tuesdays and Fridays, 6 P.M., in May, June, and July. Elements of Histology: Dr. J. Maughan, Mondays and Thursdays, 12 o'clock, May, June, and July. Surgery of the Mouth: Mr. E. W. Roughton, Monday at 5, May, June, and July. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for sixty chairs. Dresserships in the extraction rooms are re-arranged every three months. An Entrance Exhibition, of the value of £15, is open for competition at the commencement of each summer and winter session. Prizes in medals are open for competition at the end of each course of lectures. Certificates of honour are given in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the most meritorious student; and the Ash Prize, value £3 3*s.*, for a Thesis on a subject in Dental Surgery. Total fee for the Special Lectures and Hospital Practice required, 40 guineas. Single Courses: Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Mechanics, Dental Metallurgy, Dental Materia Medica, Demonstration of Dental Mechanics, £5 5*s.* each. Practical Dental Surgery, £3 3*s.* Hospital Practice to registered practitioners by special permission of Committee, twelve months, £15 15*s.* The Committee also consider applications from medical men who may desire to attend the Anæsthetic Room for a course of instruction in Nitrous Oxide administration. Information respecting the Hospital Practice and the College may be obtained from the Dean, Mr. Sidney Spokes, who attends at the Hospital, Great Portland-street, on Tuesday mornings.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. *The Extraction Rooms:* Patients are admitted between 9 and 9.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required. *The Conservation Room:* This room is open from 9 A.M. till 5 P.M. There are fifty Morrison chairs for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at this hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the special lectures and practice of the Dental Department and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. An Entrance Scholarship in Arts of the value of £30 is offered for competition annually in September, and prizes of the aggregate value of £35 are awarded for general proficiency and skill in Practical Dentistry. Dental students are eligible for admission to the Residential College and enjoy the other social privileges of students in the Medical School.

London Hospital.—Mr. Cunningham and Mr. Dolamore give practical instruction during the winter and summer sessions on Mondays, Tuesdays, Thursdays, and Fridays at 9 A.M. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department. A class for special instruction in filling teeth will be formed each term. Candidates for Dresserships must undertake to attend regularly on Mondays and Thursdays, or on Tuesdays and Fridays, for three months, and to follow the practical course of demonstrations.

Mason University College, Birmingham.—The teaching of Dentistry is undertaken by the Mason University College, acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of the Royal Colleges. There is a special and well-equipped Dental Museum and Laboratory. Special courses of lectures are delivered on Medical and Surgical Diseases of the Mouth, &c., and there is a special course of Practical Dental Histology and Pathology. An Entrance Exhibition, value £15 15*s.*, is awarded annually at the commencement of the winter session. Medals and honour certificates are awarded annually in the various classes.

Liverpool Dental Hospital, Mount Pleasant.—The Liverpool Dental Hospital, founded in the year 1864, combines the work of a most useful charity with all the advantages of a dental school recognised by all the licensing bodies of Great Britain and Ireland. The increased facilities provided by the recent extensive additions and alterations have more than fulfilled the most sanguine anticipations of the committee and staff, and students have been quick to avail themselves of the increased accommodation and conveniences. Special attention has been paid to the ventilation and lighting; the electric light alone is employed for operating during the evening. Each chair has been provided with a specially constructed canting pendant which can be fixed at any angle. The chairs are of the well-known Morrison pattern, which, together with other fittings and fixtures, render this room one of the finest in the kingdom. There is an abundant daily supply of patients. Over 23,000 cases were treated during last year. The hospital staff consists of twelve honorary dental surgeons, one of whom is present each morning and evening. In addition to these there are one or more house surgeons to superintend all the hospital work and devote themselves to clinical teaching, advising and helping the students in their studies. Every facility is afforded to students who are anxious to acquire proficiency in Dental Surgery and to prepare themselves for the Dental diploma of the Royal College of Surgeons. The fee for the two years' Dental Hospital Practice required by the Royal College of Surgeons is £12 12*s.*, which must be paid on entrance. Fee as a perpetual student, £15 15*s.* Composition fee for Lectures: a payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months). Fee for General Hospital Practice, £10 10*s.* All communications relating to the medical department should be addressed to Professor Paterson, Dean of the Medical Faculty, University College; and all communications relating to the Dental Hospital should be addressed to R. Edwards, 50, Mount Pleasant.

University College, Bristol. — Dental students can enter for the full curriculum at Bristol. The Lectures are delivered at the college. Practical instruction is given at the Royal Infirmary by Mr. Auckland and at the General Hospital by Mr. Genge, both institutions being recognised by the Dental Board of the Royal College of Surgeons of England. Full information may be obtained of the Dean of the Medical Faculty, Professor E. Markham Skerritt, University College, Bristol.

Owens College, Manchester.—Arrangements have been made for dental students to attend the hospital practice at the Manchester Royal Infirmary and the practice at the Victoria Dental Hospital. Lectures on special subjects will be given in the College as follows:—Winter session: Dental Mechanics, Mr. Tanner, Thursday, 4 P.M. Dental Metallurgy, (vacant). Summer session: Dental Anatomy and Physiology, Mr. Hooton, Tuesday at 4 P.M., Friday at 2 P.M. Dental Surgery, Mr. Campion, Tuesday and Friday, 3 P.M. Practical and Operative Dental Surgery, Mr. Whittaker, Wednesday: Lecture, 2.30 P.M.; Demonstration, 4 P.M. Lectures in Dental and Practical Histology, Mr. Headridge. Fee for the course £4 4*s.* Dental practice for two years at the Manchester Royal Infirmary, £10 10*s.*; at the Victoria Dental Hospital at Manchester, £12 12*s.*, paid in advance, or £8 8*s.* for the first year and £5 5*s.* for the second year. At the Victoria Dental Hospital patients attend at 8.30 A.M. daily, and at 7 P.M. on Monday, Wednesday, and Friday. Consulting Physicians: Dr. H. Simpson and Professor D. J. Leech. Consulting Surgeons: Mr. E. Lund, Mr. F. A. Heath, Professor T. Jones, and Mr. J. Hardie. Consulting Dental Surgeons: Mr. H. Campion and Mr. G. W. Smith. Dental Surgeons: Mr. G. G. Campion, Mr. E. P. Collett, Mr. W. Dougan, Mr. L. Dreschfeld, Mr. J. W. Dunkerley, Mr. W. Dykes, Mr. W. Headridge, Mr. W. A. Hooton, Mr. I. Renshaw, Mr. W. Simms, Mr. W. Smithard, Mr. T. Tanner, and Mr. G. O. Whittaker. Assistant Dental Surgeons: Mr. P. A. Linnell, Mr. F. W. Minshall, Mr. C. R. Morley, and Mr. C. H. Smale. Administrators of Anæsthetics: Dr. A. Wilson and Dr. J. P. Stallard. Dean: Mr. G. G. Campion.

University College, Liverpool (Liverpool Dental Hospital and School of Dental Surgery).—The courses of systematic instruction are given in University College, five minutes from the Dental Hospital. The two institutions are now closely associated and the management of the curriculum is in the hands of a joint committee. At the Dental Hospital recent alterations have been made and as it now stands this school offers advantages to students which are not excelled anywhere. The ground floor of the building contains the following: Extraction-room, with all needful appliances; anæsthetic room, specially reserved with every convenience; and large waiting-room for patients. The first floor has a large board-room and a very comfortable students' room set apart exclusively for the use of students. The whole top floor of the building has been thrown into one fine, airy, and well-ventilated operating room. This room will accommodate upwards of thirty operating chairs, which are of the "Morrison pattern," and each of which has a special electric light (canting pendant) suspended before it. In the basement a very convenient workroom has been fitted up containing the necessary requirements, and there are commodious lavatories for students. A new Laboratory for practical mechanical work is at present being constructed, so as to meet the requirements of the curriculum. A skilled Dental Mechanic will be engaged and students will be able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lectures at University College are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. The staff of the hospital includes twelve honorary Dental Surgeons, a Demonstrator, two House Surgeons, and a Curator. Fees for two years' hospital practice £12 12*s.*; perpetual £15 15*s.* The various medical and dental lectures are given at University College. The Anatomical Department contains an excellent collection of skulls illustrative of human and comparative dental anatomy. The dissecting-room and theatre are lighted by electricity. The Physiological and Pathological Department enter into occupation of new and spacious laboratories erected by the Rev. S. A. Thompson Yates. These laboratories will be opened by Lord Lister, P.R.S., on Oct. 8th. Fees: The composition fee for all lectures is £50 in one payment on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months). The fee for general hospital practice is £10 10*s.* Further particulars can be obtained of A. M. Paterson, M.D., Dean.

Devon and Exeter Dental Hospital, Castle-street, Exeter.—Established 1880.—The hospital is open daily (Sundays excepted), and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers, and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M. Ackland; hon. secretary, Mr. Henry Yeo.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School, 31, Chambers-street, Edinburgh.—For the special classes, both theoretical and practical, required by dental students the directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The fee for clinics in gold filling is included in the Dental Hospital fee of £15 15*s.* The minimum cost of classes for the whole course of dental instruction amounts to £78 13*s.*

Dental Hospital and School, Glasgow. — The summer session was opened on May 3rd, 1898, and the lectures were delivered as under:—Dental Surgery and Pathology, on Tuesdays and Thursdays, at 8 A.M. J. M. MacMillan, L.R.C.S. & P. Edin., L.D.S., lecturer. Dental Anatomy and Physiology, on Wednesdays and Fridays, at 8 A.M. Wm. Wallace, M.A., M.B., C.M., L.D.S., lecturer. The winter session opens on Nov. 1st, 1898, and the lectures will be delivered as under: Dental Mechanics, on Tuesday evenings at 7.30 P.M., beginning Nov. 2nd. Mr. John A. Biggs, L.D.S., lecturer. Fee for each of the above courses of lectures, £3 3*s.* The lectures on Dental Anatomy and Dental Surgery are arranged to extend over two summer sessions, as required by the Royal College of Surgeons of England, thus enabling students to present themselves for examination at any of the four Licensing Boards. The fees for lectures and two years' hospital practice amount to £25 4*s.* Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental students. Dean: Mr. John A. Biggs, L.D.S. Secretary: D. M. Alexander, 97, West Regent-street, Glasgow. The hospital

Digitized by Google

is open daily from 5 to 7 P.M. (Saturdays excepted). Students may enrol at any time, their period of attendance counting from date of entry.

Glasgow Royal Infirmary (Dental Department).—Mr. W. H. Gray, L.D.S., attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital; to dental students, one year, £5 5*s.*; perpetual £10 10*s.*

IRELAND.

School of the Royal College of Surgeons in Ireland.—Dentistry: Professor R. T. Stack, M.D.Univ.Dub., F.R.C.S., L.D.S.Eng., Examiner Royal College of Surgeons, Dentist Dental Hospital of Ireland. Arrangements are completed for the education of candidates for the Licence in Dental Surgery of the College, and the following courses are delivered during the session:—Dental Anatomy, Professor Fraser; Dental Metallurgy, Professor Lapper. Fee, each course, £3 3*s.*

MEDICAL TEACHERS.

MR. R. C. B. KERIN, B.A. London, first in First Class Honours in Classics, assisted by a staff of B.A. and B.Sc. Honour Graduates, prepares candidates in class and by private Tuition for Medical Preliminaries, London Matriculation, Preliminary Scientific Inter. Science, Hospital Scholarships, First Conjoint, First M.B.Lond., Oxon., and Camb., &c. Biological, Chemical, and Physical Laboratories. For last six years 150 London University Successes and 3 Hospital Science Scholarships, &c.—Carlyon College, 55 and 56, Chancery-lane, W.C.

The UNIVERSITY EXAMINATION POSTAL INSTITUTION prepares candidates through the post or orally for all Medical Examinations, especially for the M.D. (London or Durham) and the D.P.H. (Cambridge or London). There are five medical tutors, of whom three are Medallists of the London University. Preparation also by the other tutors for the Preliminary Arts or Science Examinations. Numerous recent successes. — Manager, Mr. E. S. Weymouth, M.A., 27, Southampton-street, Strand, London, W.C.

M.D., B.S. LOND., prepares for all the Professional Exams. Small classes are held for the Final College of Surgeons and Physicians, the Hall, the M.D.'s of Brussels and Durham (fifteen years' standing). Tuition by correspondence. — Address, M.D., 23, Wimpole-street, Cavendish-square, W.

Special preparations, in class, privately, and by correspondence, for the Triple Qualification, Edinburgh. Also for Fellowship Examinations of Royal College of Surgeons, Edinburgh, and M.D. Brussels. Resident pupils received.—Address, CLASS ROOMS, 7, Chambers-street, Edinburgh.

Coaching for Examination (University of Brussels). Also Correspondence Course for Provincial Practitioners, with practical and *viva voce* work in London before going to Brussels.—Address, CANTAB., THE LANCET Office, 423, Strand, W.C.

Mr. BECKTON (late 19, Keppel-street, W.C.) has removed to 61, Torrington-square, Russell-square, W.C., where he continues to prepare candidates for Matriculation and Professional Preliminary Examinations, and the 1st Conjoint. Boarders received.

Private Tuition in Materia Medica, Chemistry (Practical and Theoretical), Physics, and Pharmacy for all Exams. Classes recognised by General Medical Council and Apothecaries' Hall. Tuition by Correspondence. Numerous successes.—Mr. SKERRY, M.A., The City School of Chemistry, 27, Chancery-lane.

Classes for the Navy Medical Service are held at 46, Great Ormond-street, W.C. Those for the November Competitions begin on Monday, Sept. 19th, at 11 A.M.—H. R. JENNINGS, Sec.

Ordinary and Revision Courses in Chemistry, Physics, and Biology, for Prelim. Sci. (M.B.) and Courses in Organic Chemistry for Inter. M.B., are held at the UNIVERSITY TUTORIAL COLLEGE, Red Lion-square, Holborn. Last year 124 students of the University Tutorial College passed the Prelim. Sci. Examination of London University. Particulars may be had from the Vice-Principal, University Tutorial College, Red Lion-square, Holborn.

INSTRUCTORS IN ELOCUTION, &c.

Professor ALTSCHUL, Ph.D., has made Stammering, Stuttering, Lisping, Falsetto, recent or of long standing, due to nervousness, &c., irrespectively of age or sex (without any mechanical appliances), his special life-long study. The voice greatly developed and strengthened.—9, Old Bond-street, W. (Attends at Brighton.)

Mr. WILLIAM VAN PRAAGH, the public introducer of the Pure Oral System of Teaching Deaf Mutes, has made the subject of Lip-reading and the cure of all Defects of Speech, both acquired and congenital, his special study. Papers on the various subjects can be had at 11, Fitzroy-square, W.

Mrs. EMIL BEHNKE gives instruction in Voice Training and treats Stammering and other Defects of Speech at 18, Earl's-court-square, S.W.

Miss BOULTBEE, 37, Gloucester-place, Portman-square, W., gives Lessons in Lip-reading to persons wholly or partially Deaf.

THE STUDENT'S LIBRARY.

THE number of medical works available to the English student has now become so large, while their general quality is so excellent, that it is a matter of increasing difficulty to make any attempt to indicate the most serviceable text-book in any branch. For some years past we have endeavoured to make such a guide by taking the leading examinations as the basis of our comments and pointing out some of the chief text-books which may be read in preparation for these examinations. But for the reason above stated this mode of dealing with the matter has the objection of making a somewhat invidious selection. In what follows we propose merely to arrange in systematic fashion most of the publications now in vogue under each subject of the curriculum. We do not pretend to have made the list exhaustive and we can quite understand that there are books omitted from it which others besides the authors and the publishers know to be standard works. But we can say without fear of contradiction that any student who masters the contents of the library we here suggest for his use will know enough and to spare to pass his examinations.

ANATOMY.

THE standard text-books on Systematic Anatomy are Quain's and Gray's. Both of these have been recently brought up to date. Quain's is the more scientific work, and is, indeed, the most advanced and comprehensive treatise on the subject in the English language, if not in all languages. Its morphological, histological, and visceral anatomy is unequalled. The volume on Embryology by Professor E. A. Schäfer is the clearest and best history of development with which we are acquainted. An appendix has been published on Superficial and Surface Anatomy by Professor Thane and Professor Godlee. The work is now published in separate parts.

Quain's (Jones) Elements of Anatomy. London: Longmans, Green, and Co. The tenth edition. Edited by EDWARD ALBERT SCHÄFER, F.R.S., Professor of Physiology and Histology in University College, London; and GEORGE DANCER THANE, Professor of Anatomy in University College, London. In three volumes. Vol. I., Part I. Embryology. By Professor Schäfer. Illustrated by 200 Engravings, many of which are coloured. 9*s.* Vol. I., Part II. General Anatomy or Histology. By Professor Schäfer. Illustrated by nearly 500 Engravings, many of which are coloured. 12*s.* 6*d.* Vol. II., Part I. Osteology. By Professor Thane. Illustrated by 168 Engravings. 9*s.* Vol. II., Part II. Arthrology, Myology, Angeiology. By Professor Thane. Illustrated by 255 Engravings, many of which are coloured. 18*s.* Vol. III., Part I. Spinal Cord and Brain. By Professor Schäfer. Illustrated by 139 Engravings. 12*s.* 6*d.* Vol. III., Part II. The Nerves. By Professor Thane. Illustrated with 102 Engravings, many of which are coloured. 9*s.* Vol. III., Part III. Organs of the Senses. By Professor Schäfer. Illustrated by 178 Engravings. 9*s.* Vol. III., Part IV. Splanchnology. By E. A. Schäfer, F.R.S., and Johnson Symington, M.D. With 337 Illustrations. 16*s.* Appendix. Superficial and Surgical Anatomy. By Professor G. D. Thane and Professor R. J. Godlee. With 29 Illustrations. 6*s.* 6*d.*

Anatomy, Descriptive and Surgical. By HENRY GRAY, F.R.S., late Lecturer on Anatomy at St. George's Hospital. The fourteenth edition. 36*s.* London: Longmans, Green, and Co. Re-edited by T. PICKERING PICK, Surgeon to St. George's Hospital, Member of the Court of Examiners, Royal College of Surgeons of England. There are 705 large Woodcut Illustrations, a large proportion of which are coloured, the arteries being coloured red, the veins blue, and the nerves yellow. The attachments of the muscles to the bones in the section on Osteology are also shown in coloured outline.—*Gray's Anatomy* occupies a place only second to Quain's. In popularity it is doubtful if it does not actually precede its larger rival, and for mere everyday work it has points of superiority; in many instances the diagrams are much clearer, if somewhat more diagrammatic, excessive detail being omitted.

Digitized by Google

Human Anatomy: a Treatise by various Authors. Edited by HENRY MORRIS, M.A., M.B. Lond., F.R.C.S., Surgeon to, and Lecturer on Surgery at, the Middlesex Hospital, with 800 Illustrations, nearly all original, and many of them in several colours. 36*s.* Second edition.—This is an excellent work. We may mention especially the description of the peritoneum, in which the arrangement of that complicated structure is set out with admirable clearness. In one volume. London: J. & A. Churchill.

A Manual of Anatomy for Senior Students. By EDMUND OWEN, M.B., F.R.C.S., Senior Surgeon to the Hospital for Sick Children, Great Ormond-street, Surgeon to St. Mary's Hospital, London, and co-Lecturer on Surgery, late Lecturer on Anatomy, in its Medical School. With 210 Illustrations. Price 12*s.* 6*d.* London: Longmans, Green, and Co.

A Text-book of Human Anatomy: Systematic and Topographical. By ALEXANDER MACALISTER, M.A., M.D., F.R.S., F.S.A., Professor of Anatomy in the University of Cambridge, and Fellow of St. John's College, Examiner in Human Anatomy, University of London. Includes the Embryology, Histology, and Morphology of Man, with special reference to the requirements of Practical Surgery and Medicine. One vol. 1889. 816 Illustrations. 36*s.* London: Charles Griffin and Co.—It is in many respects the most important work on the subject that has appeared in recent years, being thoroughly comprehensive, lucid, and up to date. It is especially suited for senior students.

Wilson's Anatomist's Vade-Mecum. Eleventh edition. By HENRY E. CLARK, M.R.C.S. Eng., F.F.P.S. Glasg., Examiner in Anatomy, F.P.S., and Professor of Surgery in St. Mungo's College, Glasgow. With 492 Engravings and 26 Coloured Plates. 18*s.* London: J. & A. Churchill.

The Anatomy of the Joints of Man. By HENRY MORRIS, F.R.C.S. 8vo. 16*s.* London: J. & A. Churchill.—This is perhaps the most complete book on the subject yet published. The work is fully illustrated, and many of the illustrations are in colour. Besides the bones, ligaments, and synovial membranes, the various features connected with the arterial and nervous supply of the joints, the bursæ, and the muscles which act upon the joints are very thoroughly dealt with.

In Practical Anatomy the student has the choice of text-books by Ellis, Cunningham, Heath, and Cleland. The favourite dissecting-room manuals are probably those of Ellis and Cunningham.

Ellis's Demonstrations of Anatomy, as edited by Professor THANE, have been studied by generations of dissectors, and for accuracy and thoroughness leave nothing to be desired.—*Cunningham's Practical Anatomy* is a very clear, well-written book, and fully illustrated. It has the advantage of being published in separate volumes. It is steadily growing in favour and has many points of superiority.—*Heath's Practical Anatomy* is a smaller work, clearly written, and forming a compendious introduction to the subject.

Demonstrations of Anatomy. By GEORGE VINER ELLIS, F.R.C.S. Eleventh edition. 1890. Pp. 782. 12*s.* 6*d.* London: Smith, Elder, and Co.

Cunningham's Manual of Practical Anatomy. Second edition. In two vols., cloth, illustrated with 372 Wood Engravings and two Coloured Plates. Vol. I.: Upper Limb, Lower Limb, Abdomen; Vol. II.: Thorax, Head, and Neck. Price 12*s.* 6*d.* each volume. Edinburgh: Young J. Pentland.

Heath's Practical Anatomy. Edited by W. ANDERSON, F.R.C.S. With 329 Engravings. 15*s.* London: J. & A. Churchill.

Surgical Anatomy: a Manual for Students. By A. MARMADUKE SHEILD, M.B. Cantab., F.R.C.S. Crown 8vo, cloth, pp. xii.-226. 1891. 6*s.* Edinburgh: Young J. Pentland.

Dissections Illustrated. By C. GORDON BRODIE, F.R.C.S. A graphic handbook for students of anatomy; 73 Coloured Plates and 37 Diagrams. 42*s.* London and New York: Whittaker and Co. It is also published in four parts.—This is an admirable book and should find a place in every student's library.

Applied Anatomy may be studied from the works of Treves, Bellamy, Holden, or Maclachlan.

Holden's Landmarks, Medical and Surgical, like all his work, is distinguished by its clearness of arrangement and correctness of detail. The English is perfect and the illustrations excellent. It thoroughly justifies its popularity in every way.—*Treves's Surgical Applied Anatomy* and the *Guide to Surgical Anatomy* by EDW. BELLAMY are both in general use in our schools. The former is particularly full of information, conveyed in such a way that it is likely to stay in the student's memory.—*Maclachlan's Surgical Anatomy* is better known in Scotland. It is an accurate and comprehensive work.

Landmarks, Medical and Surgical. By LUTHER HOLDEN, F.R.C.S. Fourth edition. 3*s.* 6*d.* London: J. & A. Churchill.

Surgical Applied Anatomy. By F. TREVES, F.R.C.S. Pp. 574, with 61 Engravings. 16th thousand. 1894. 7*s.* 6*d.* London: Cassell and Co.

Human Osteology. By LUTHER HOLDEN, F.R.C.S. Edited by Professor Stewart and Robt. W. Reid, M.D. Seventh edition. With 59 Plates. 16*s.* London: J. & A. Churchill.

Aphorisms in Applied Anatomy and Operative Surgery: including 100 Typical vivâ-voce Questions on Surface Marking, &c. By THOMAS COOKE, F.R.C.S. Crown 8vo. 3*s.* 6*d.* London: Longmans, Green, and Co.

Dissection Guides. Aiming at extending and facilitating such practical work in anatomy as will be specially useful in connexion with an ordinary hospital curriculum. By THOMAS COOKE. 8vo. 10*s.* 6*d.* London: Longmans, Green, and Co.

Tablets of Anatomy. By THOMAS COOKE, F.R.C.S.—These tablets are designed to help the student to retain what he has acquired in studying either in dissection or from the text-books. A new edition, abundantly illustrated and containing full digests of the results of recent anatomical investigations, is now ready. London: Longmans, Green, and Co.

PHYSIOLOGY.

Text-book of Physiology. By Professor MICHAEL FOSTER, M.D., F.R.S. Four parts. Pp. 1550. With an Appendix. *The Chemical Basis of the Animal Body,* constituting a separate volume of 270 pages, by A. SHERIDAN LEA, D.Sc., F.R.S. The best English text-book of the subject; suitable for students preparing for higher examinations. Deals with histology as well as with physiology proper. The parts can be bought separately. Part I., The Blood, Tissues of Movement, and Vascular Mechanism. 10*s.* 6*d.* Part II., The Tissues of Chemical Action and Nutrition. 10*s.* 6*d.* Part III., The Central Nervous System. 10*s.* 6*d.* Thoroughly revised and brought up to present date. Part IV., The Tissues and Mechanisms of Reproduction. 10*s.* 6*d.* Appendix, 7*s.* 6*d.* Sixth edition. London: Macmillan and Co. 1895.

An Introduction to Human Physiology. By AUGUSTUS WALLER, M.D., F.R.S.—A very complete manual, though of medium size; thorough and attractively written in all its parts; presupposes good acquaintance with chemistry and physics; well suited to meet medical and other examinations in the subject, but containing very little histology; with 314 illustrations. Third edition. 1896. Pp. 640. London: Longmans, Green, and Co. Price 18*s.*

Text-book of Physiology. By British Physiologists. Edited by E. A. SCHÄFER, F.R.S., Jodrell Professor of Physiology, University College, London. Two vols., royal 8vo. Vol. I., pp. xx.-1036, with 3 Plates and 93 Illustrations in the text. Price 31*s.* 6*d.* Vol. II. in Press. 1898. The following among others will contribute: Professor Burdon Sanderson (Oxford), Professor Gamgee, Dr. Gaskell (Cambridge), Professor Gotch (Oxford), Professor Sherrington (Liverpool), Professor M'Kendrick (Glasgow), Professor Halliburton (King's College), Professor Haycraft (Cardiff), Dr. Pembrey (Charing-cross), Dr. Starling (Guy's), Dr. Rivers (Cambridge), J. N. Langley (Cambridge), Professor Waymouth Reid (Dundee), B. Moore (University College), F. G. Hopkins (Guy's), Leonard Hill (London Hospital), W. H. R. Rivers (Cambridge), the Editor, &c. Edinburgh: Young J. Pentland.

A Manual of Physiology for Students and Practitioners. By Professor G. N. STEWART, M.A., D.Sc., M.D., D.P.H. Camb.—A first-class text-book of medium size; profusely illustrated; deals fully with medical physiology; contains a number of practical exercises; also some well-coloured histological plates; thoroughly commendable. Pp. 795. London: Baillière, Tindall, and Cox. 1895. Price 15*s.*

Digitized by Google

Kirkes' Handbook of Physiology. Edited by W. D. HALLIBURTON, M.D., F.R.S.—This book may be regarded as a thoroughly reliable exposition of the present state of physiological knowledge. Fourteenth edition. Revised. London: J. Murray. 1896. 14*s.*

Human Physiology. By Professor LANDOIS. Translated and edited by WILLIAM STIRLING, M.D., D.Sc. Fifth edition in active preparation. London: Charles Griffin and Co. 1891.

Text-book of Physiology. By JOHN GRAY MCKENDRICK, M.D., F.R.S. A large work, containing in some directions more than the student requires, but a first-class treatise. 40*s.* Two vols. Glasgow: Maclehose and Sons.

Manual of Physiology. By G. F. YEO, M.D., F.R.S. A good book, somewhat smaller than the foregoing. 14*s.* Third edition. London: J. & A. Churchill.

Elements of Human Physiology. By ERNEST H. STARLING, M.D., M.R.C.P., Joint Lecturer on Physiology at Guy's Hospital. Third edition, with 140 Engravings. 7*s.* 6*d.* London: J. & A. Churchill. Outlines; no histology.

Physiology for Beginners. By Professor MICHAEL FOSTER, M.D., F.R.S., and LEWIS E. SHORE, M.A., M.D.—A capital little book, forming a good introduction to Foster's "Text-book" or to Waller's "Human Physiology." Extremely clearly written and thoroughly illustrated. Not sufficient by itself to meet the requirements of medical examinations in physiology or histology. 2*s.* 6*d.* London: Macmillan and Co. 1894.

Notes on Physiology for the Use of Students preparing for Examination. By HENRY ASHBY, M.D. Lond., F.R.C.P., Physician to the General Hospital for Sick Children, Manchester; formerly Demonstrator of Physiology, Liverpool School of Medicine. Sixth edition, thoroughly revised. With 141 Illustrations. Fcap. 8vo, price 5*s.* London: Longmans, Green and Co.

The Essentials of Experimental Physiology. For the Use of Students. By T. G. BRODIE, M.D., Lecturer on Physiology, St. Thomas's Hospital Medical School. With 2 Plates and 177 Illustrations. 8vo. 1898. 6*s.* 6*d.* London: Longmans, Green and Co.

PHYSIOLOGICAL CHEMISTRY.

A Text-book of the Physiological Chemistry of the Animal Body. By ARTHUR GAMGEE, M.D. Edin., F.R.S. Vol. II., Digestion.—The best manual on the subject, but only suitable for advanced students. 1892. 18*s.* London: Macmillan and Co.

Text-book of Chemical Physiology and Pathology. By Professor W. D. HALLIBURTON, M.D., F.R.S.—An excellent manual for all students. Illustrated. One vol. 1891. 28*s.* London: Longmans, Green, and Co.

Essentials of Chemical Physiology. By the same author.—An excellent and indispensable manual for students in the physiological laboratory. It is a very handy size, 170 pp. 1896. Price 5*s.* London: Longmans, Green, and Co.

The Chemical Basis of the Animal Body. By A. SHERIDAN LEA, D.Sc., F.R.S.—A first-rate treatise, constituting the appendix to Foster's Physiology. Smaller, less illustrated, and less expensive than either of the foregoing text-books, containing very complete references to original papers. One vol. Pp. 270. 1892. 7*s.* 6*d.* London: Macmillan and Co.

HISTOLOGY AND EMBRYOLOGY.

Some physiological text-books deal with Histology sufficiently fully for the pass examinations of the medical student; such books are Foster, Landois, and Kirkes (see above). The histological descriptions in Quain's "Anatomy" are unsurpassed. Special treatises are:—

Histology. By E. A. SCHÄFER, F.R.S., Jodrell Professor of Physiology in University College, London; Editor of the Histological Portion of Quain's "Anatomy." Second edition. Revised and enlarged. 1897. 7*s.* 6*d.* London: Smith, Elder, and Co.

The Elements of Embryology. By Professor MICHAEL FOSTER, F.R.S., and the late Professor FRANK BALFOUR, F.R.S. Second edition, revised. Pp. 470. 1893. 10*s.* 6*d.* Eminently practical; the best book for those examinations in which practical work and manual skill in the subject are required.—*Practical Physiology.* By Professors MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Sixth edition. 1895. 7*s.* 6*d.* An excellently selected series of laboratory exercises, with full instructions to the student. Both, London: Macmillan and Co.

The Essentials of Histology: Descriptive and Practical. For the Use of Students. By E. A. SCHÄFER, LL.D., F.R.S. Illustrated by nearly 400 Figures. Fifth edition, revised and enlarged. 8vo. 1898. 8*s.* (Interleaved, 10*s.* 6*d.*). London: Longmans, Green, and Co.

Outlines of Practical Physiology. By Professor WILLIAM STIRLING, D.Sc. Third edition. 1895. 12*s.* 6*d.* Thoroughly revised and partly re-written, with additional illustrations. Includes chemical and experimental physiology and references to practical medicine; histology not included; the best students' book on the subject; full of information and capitally illustrated.—*Outlines of Practical Histology.* Second edition. 1892. 12*s.* 6*d.* Companion volume to the above and equally good; copiously illustrated. Both, London: Charles Griffin and Co.

Text-book of Histology. By A. CLARKSON, M.B., C.M. Edin. A useful student's book, with 200 excellent illustrations, most of them well coloured. Bristol: Wright. 1896. 21*s.*, or plates only, with descriptions, 9*s.* net.

Text-book of Morbid Histology. By Professor RUBERT BOYCE. With 130 Coloured Illustrations. 1892. 31*s.* 6*d.* London: H. K. Lewis.

Atlas of Human Anatomy. By Dr. ARNOLD BRASS, Göttingen. Translated by R. A. YOUNG, M.D., B.Sc. Sixty plates, containing 500 accurately coloured drawings of sections. London: Baillière, Tindall, and Cox. 1897. 31*s.* 6*d.* net.

Elements of Histology. By E. KLEIN, M.D., F.R.S., and J. S. EDKINS, M.A., M.B. With 296 Illustrations. 7*s.* 6*d.* London: Cassell and Co.

There are also two small books dealing with histological methods which will be found useful by students and hospital residents:—

Methods and Formulæ. By PETER WYATT SQUIRE. London: J. & A. Churchill.

Section Cutting and Staining. By W. S. COLMAN, M.D. Second edition, revised. 1896. London: H. K. Lewis.

CHEMISTRY AND PHYSICS.

Chemistry: General, Medical, and Pharmaceutical. By JOHN ATTFIELD, F.R.S.—A very serviceable manual both for preparation work and reference. It has been designed especially for medical and pharmaceutical students, treats at fair length of both inorganic and organic chemistry, and contains useful data on the analysis and examination of drugs and morbid products—as, for example, calculi, urine, and blood. Seventeenth edition. Revised in accordance with the new Pharmacopœia. 15*s.* London: Gurney and Jackson.

Organic Chemistry. By IRA REMSEN.—A clear account of the principles, including also the preparation of important organic substances. 6*s.* 6*d.* London: Macmillan and Co.

Notes on Analytical Chemistry for Students of Medicine. By A. J. BERNAYS.—This is an excellent laboratory book for medical students preparing for examination, and contains also data of service to the practitioner—as, for example, the methods of examination of urinary deposits, the estimation of sugar, and the detection of biliary constituents, &c., in urine. Third edition. 4*s.* 6*d.* London: J. & A. Churchill.

Practical Organic Chemistry. By S. RIDEAL, D.Sc.—A very handy little book for use in the laboratory. It covers all the ground of the London synopsis. Second edition. 2*s.* 6*d.* London: H. K. Lewis.

Physics for Students of Medicine. By ALFRED DANIELL, M.A., D.Sc.—This is a recently published work by Professor Daniell, whose experience of the requirements of medical students in regard to physics is well known. It will be found an excellent companion to lecture work and is suitable for students preparing for the elementary physics examination of the Conjoint Board. It is published by Macmillan and Co., price 4*s.* 6*d.* For the first M.B. Lond. students should possess a copy of the more advanced work—*A Text-book of Physics.* Third edition. 21*s.* By the same author and publisher.

A Manual of Physics. By WILLIAM PEDDIE, D.Sc., F.R.S.E. Second edition (revised and enlarged). London: Baillière, Tindall, and Cox. 1896. Price 7*s.* 6*d.*—This handy-sized volume will be found a very useful companion to those

Digitized by Google

reading for the London University examinations and the Conjoint Board. It belongs to the University series. It is written to the level of junior students or of schoolboys of a fair average intelligence, but for that reason, we think, might have been more fully illustrated.

Elementary Lessons in Electricity and Magnetism. By SYLVANUS THOMPSON, D.Sc. A standard text-book on the subject. 4*s.* 6*d.* London: Macmillan and Co.

MATERIA MEDICA AND THERAPEUTICS.[1]

Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S. Third edition, containing the additions (1891) to the British Pharmacopœia, 21*s.*; in two vols., 22*s.* 6*d.* Supplement separately, 1*s.* London: Macmillan and Co.—The student for the higher examinations would be well advised to provide himself with this work. It is equally useful as a practical treatise and as a work of reference and is admirably written. It is not intended for junior students.

A Handbook of Therapeutics. By SIDNEY RINGER, M.D., F.R.C.P., F.R.S. This is another large and important work, designed more for reference than for daily use. Thirteenth edition. London: H. K. Lewis.

Manual of Pharmacology and Therapeutics. By WILLIAM MURRELL, M.D., F.R.C.S. Price, 10*s.* 6*d.* London: Baillière, Tindall, and Cox.

Materia Medica. By HALE WHITE, M.D., F.R.C.P., Physician to Guy's Hospital. Third edition, based upon the 1898 Pharmacopœia. London: J. & A. Churchill. 7*s.* 6*d.*

Materia Medica and Therapeutics. An Introduction to the National Treatment of Disease. By J. MITCHELL BRUCE, M.D., F.R.C.P. Thirty-third thousand. Pp. 582. Price 7*s.* 6*d.* London: Cassell and Co. 1896.—Two excellent practical books for students engaged in any of the pass examinations.

Essentials of Materia Medica and Therapeutics. By Sir A. B. GARROD, M.D., F.R.S., &c. Fourteenth edition. 1895. Edited by NESTOR TIRARD, M.D., F.R.C.P. The subject is regarded entirely from a practical therapeutic point of view, and the work, though more useful to the practitioner, can still be used as a book of reference by the student. 12*s.* 6*d.* London: Longmans, Green, and Co.

Of other text-books likely to be of value we might mention:—*Materia Medica and Therapeutics: Inorganic Substances.* By C. D. F. PHILLIPS, M.D. Second edition. 8vo. 21*s.* London: J. & A. Churchill.—*Guide to Therapeutics.* By R. FARQUHARSON, M.D., F.R.C.P., &c. Fifth edition. Pp. 417. 7*s.* 6*d.* London: Smith, Elder, and Co. 1891.—*Materia Medica and Therapeutics.* By Dr. BARTHOLOW. Ninth edition. Pp. 866. 21*s.* London: H. K. Lewis. 1896.—*The Dictionary of Treatment.* By WM. WHITLA, M.D. Q U.I. Fourth edition. Pp. 1000. 16*s.* London: Henry Renshaw. 1898. A capital, practical book, and pleasant reading.—*Notebook on Materia Medica.* By SCORESBY JACKSON. New edition. Edited by RALPH STOCKMAN, M.D., and J. RUTHERFORD HILL. London: J. Thin.

MEDICINE.

The number of text-books on Medicine is so large, and their general excellence so high, that it is impossible to make a selection with which no one could find legitimate fault. It must always appear that some books as good or better than the specified list have been omitted. We do not for a moment pretend that this is the best possible list, but the student who is guided by these books will be in very good hands.

The list might be considerably extended were works dealing with special branches of medicine included. To the aspirant for high medical degrees it may be a matter of moment to make himself familiar with some of these, such as Gowers on the Nervous System, Ashby and Wright on Diseases of Children, Goodall and Washbourn on Fevers; whilst he would find it valuable to refer to special treatises on diseases of the throat, dermatology, and other branches of medicine when engaged in the practical study of the subject. But our purview is not intended to embrace the whole field of medical literature, and the library of the medical school will afford him ample opportunity for consulting such works if need be. His own library should consist of a few selected general text-books, with the contents of which he should make himself thoroughly familiar.

[1] It must be remembered that owing to the recent publication of the new edition of the British Pharmacopœia many of the statements in these books will require modification or omission.

Text-book of the Principles and Practice of Medicine. By the late HILTON FAGGE, M.D., F.R.S., and P. H. PYE-SMITH, M.D., F.R.C.P., F.R.S. Third edition. 40*s.* London: J. & A. Churchill. Two vols.—A work of great interest mainly based on the author's personal experience as physician to Guy's Hospital as well as his wide knowledge of the literature of medicine. It is almost indispensable to the advanced student.

A System of Medicine by Many Writers. Edited by T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., LL.D. Glasg., F.R.C.P. Lond., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge. Seven vols. Each 25*s.* net. London: Macmillan and Co.—Five volumes of this admirable work have now appeared. In scope and character it resembles the well-known "System" edited by the late Sir J. Russell Reynolds. The articles are replete with information and embrace the latest teachings of science. It should be invaluable to the practitioner as well as to the candidate for higher degrees.

A Text-book of the Theory and Practice of Medicine. By American Teachers. Edited by WILLIAM PEPPER, M.D., LL.D. Two vols. 1893. Pp. 909 and 1046. Philadelphia: W. B. Saunders. London: The Rebman Publishing Company.

The Theory and Practice of Medicine. By the late J. S. BRISTOWE, M.D., F.R.S. Seventh edition. 1890. Pp. 1285. 21*s.* London: Smith, Elder, and Co.—A work of sterling merit by a highly-esteemed physician; perhaps more full in clinical and pathological exposition than in therapeutical, but thoroughly sound in teaching.

The Theory and Practice of Medicine. By F. T. ROBERTS, M.D. Ninth edition. 21*s.* London: H. K. Lewis.—Long a deserved favourite with students, for whom it is especially written. Its great feature is the remarkably systematic division of the subject matter; replete with facts, but somewhat restrained in style.

A Medical Handbook for Practitioners and Students (Griffin's "Pocket-book Series.") By R. S. AITCHISON, M.D. Edin., F.R.C.P. Third edition, with numerous Illustrations.—This is an excellent little book which can be carried in the pocket. It is well adapted for ready reference.

The Principles and Practice of Medicine. By W. OSLER, M.D. Third edition. 1895. 25*s.* London: Young J. Pentland.—This work is one of the best text-books now available; it is clearly and pleasantly written, and is thoroughly up to date in science and practice.

Manual of the Practice of Medicine. By F. TAYLOR, M.D., F.R.C.P. Fourth edition, with Thirty Engravings. Pp. 958. 15*s.* London: J. & A. Churchill.—Perhaps the most widely read of all text-books in the present day, sharing with Osler's work the favour of the student, who is fortunate to have such sound and useful works at his disposal.

The Practice of Medicine. By JAMES TYSON, M.D. 1896. Pp. 1184. Philadelphia: Blakiston. Manchester: J. K. King and Son.

The Practice of Medicine. By HORATIO C. WOOD, A.M., M.D., LL.D., and REGINALD H. FITZ, A.M., M.D. 1897. Pp. 1088. 21*s.* London and Philadelphia: J. B. Lippincott Co.

Text-book of Medicine. By Professor STRÜMPELL. Second edition. 1893. Pp. 1053. 28*s.* London: H. K. Lewis.—A work of great merit, representing the German school; in originality nearly approaching to the famous text-book of Niemeyer, which was highly appreciated twenty years ago.

Dictionary of Medicine. Edited by Sir RICHARD QUAIN, Bart., M.D. Lond., LL D. Edin., F.R.S., assisted by F. T. ROBERTS, M.D., F.R.C.P., and J. MITCHELL BRUCE, M.D., F.R.C.P. Two vols. 1895. 40*s.* nett. London: Longmans, Green, and Co.—The arrangement of this work is such that the subjects can be readily selected for study, and the thorough revision to which it has been subjected renders it in all respects a trustworthy guide. The contributors are all of them physicians well qualified to speak on the subjects assigned them.

Dictionary of Practical Medicine. By J. K. FOWLER, M.D., F.R.C.P. 21*s.* London: J. & A. Churchill.—A very useful book of reference for the student and busy practitioner.

Elements of Practical Medicine. By A. H. CARTER, M.D., F.R.C.P. Seventh edition. 1895. Pp. 496. 10*s.* London: H. K. Lewis.

Digitized by Google

Student's Guide to Practice of Medicine. By M. CHARTERIS, M.D., L.R.C.S. Edin., &c. Seventh edition. With Engravings. 10*s.* London: J. & A. Churchill.

An Index of Medicine: a Manual for the Use of Senior Students and Others. By SEYMOUR TAYLOR, M.D., M.R.C.P., Senior Assistant Physician to the West London Hospital. With Illustrations. Pp. 808. 12*s.* 6*d.* London: Smith, Elder, and Co.—The foregoing works are well planned; without being exhaustive, they present the salient facts of medicine in a concise form, and may well be chosen by the beginner.

Medical Diagnosis. By J. M. DA COSTA, M.D., LL.D. Eighth edition. 1896. London: Smith, Elder, and Co.—The leading text-book on diagnosis, replete with practical information.

Medical Diagnosis. By J. H. MUSSER, M.D. With 162 Engravings and 2 Coloured Plates. Pp. 882. Price 24*s.* 1894. Edinburgh and London: Young J. Pentland.—A voluminous work, less practical than Da Costa's treatise, and resembling rather a systematic manual of medicine, confined to diagnostic points.

Clinical Medicine. By JUDSON BURY, M.D., F.R.C.P. Price 21*s.* London: Charles Griffin and Co.—A very admirable and clearly written work, fully illustrated.

Clinical Manual. By JAMES FINLAYSON, M.D., F.F.P.S. Glasg. Third edition. 1891. Pp. 719. 8*s.* 6*d.* London: Smith, Elder, and Co.—One of the earliest works of its class, thorough and systematic.

Manual of Medical Diagnosis. By Professor H. VIERORDT. With 178 Engravings, many in colour. 1892. Pp. 700. 18*s.* Edinburgh and London: Young J. Pentland.—A translation of a systematic work on diagnosis, which has just reached a fifth edition in the original.

Medical Diagnosis: A Manual of Clinical Methods. By J. J. GRAHAM BROWN, M.D., F.R.C.P., F.R.S. Edin. Fourth edition. Pp. 428. 9*s.* Edinburgh: Wm. F. Clay.—A sound and reliable manual.

Fenwick's Students' Guide to Medical Diagnosis. Edited by S. FENWICK M.D., and W. SOLTAU FENWICK, M.D. Eighth edition. With 135 Engravings. 9*s.* London: J. & A. Churchill.—This manual has long enjoyed undivided favour; an excellent guide for practical clinical work.

Physical Diagnosis: A Guide to Methods of Clinical Investigation. By G. A. GIBSON, M.D., F.R.C.P. Edin., and WILLIAM RUSSELL, M.D., F.R.C.P. Edin. Second edition. With 109 Illustrations, many coloured. 1893. Pp. 383. 10*s.* 6*d.* Edinburgh and London: Young J. Pentland.—Contains a good exposition of the rationale of the physical signs of disease.

Auscultation and Percussion. By SAMUEL J. GEE, M.D., F.R.C.P. Fourth edition. 1893. Pp. 327. 6*s.* London: Smith, Elder, and Co.—An original and helpful manual for the clinical observer.

Cardiac Outlines. By WILLIAM EWART, M.D., F.R.C.P. With 62 Illustrations. 1892. Pp. 165. 5*s.* 6*d.* London: Baillière, Tindall, and Cox.—Useful as a guide to the thorough examination of cardiac disease and the record of physical signs.

Clinical Diagnosis. By Professor R. VON JAKSCH. Third edition. Translated and edited by JAMES CAGNEY, M.D., M.R.C.P. 25*s.* London: Charles Griffin and Co.—A work of world-wide reputation, dealing exhaustively with microscopical and chemical aids to diagnosis.

A Manual of Clinical Diagnosis. By CHARLES E. SIMON, M.D. Second edition. 1898. London: Henry Kimpton.—Covers the same ground as the classical treatise of von Jaksch; admirably suited for the clinical laboratory.

Guide to Examination of Urine. By J. WICKHAM LEGG, M.D., F.R.C.P. Seventh edition. 1893. Pp. 136. 3*s.* 6*d.* London: H. K. Lewis.

Notes on Examination of Blood and Fæces. By SIDNEY COUPLAND, M.D., F.R.C.P. Third edition. 1892. Pp. 64 1*s.* 6*d.* London: H. K. Lewis.—Examples of a large class of small and concise manuals intended to assist the ward clerk in his daily observations.

SURGERY.

The standard English text-book on Surgery for the student is the tenth edition of *Erichsen's Science and Art of Surgery.* It has been brought well up to date. It is comprehensive, but not diffuse, and no student will ever regret having mastered it. *Walsham's Theory and Practice of Surgery*, though useful for a student commencing the study of the subject, and sufficiently full for the minor examinations in surgery, is by no means sufficient for any of the higher examinations. It is careful and exact. A very recent text-book is Rose and Carless's *Manual of Surgery.* It is trustworthy, and sufficient for all except the most advanced examinations. Spencer's *Outlines of Practical Surgery* is a valuable recent work for the student. There are several larger treatises on surgery suitable for the more advanced student; of these the latest is *Treves's System of Surgery;* it is excellently printed, very accurate, and fully up to date. *Holmes and Hulke's System of Surgery*, though no recent edition of it has appeared, is still valuable, as it contains numerous excellent authoritative monographs. *Heath's Dictionary of Practical Surgery* is also useful for reference. For Operative Surgery *Jacobson's Operations of Surgery* is an admirable text-book. The information given includes, in addition to the descriptions of the operations, the reasons for their performance. *Treves's Manual of Operative Surgery* is also excellent, and one of the two should be read by all candidates for any of the higher examinations. *Treves's Student's Handbook of Surgical Operations* gives a short but careful account of the ordinary operations, and is well worth using as a text-book in a course of operative surgery. Waring's *Manual of Operative Surgery* is an excellent work and gives the student a good insight into this important branch of the subject. There are numerous other works on surgery, such as those of Bryant, Mansell Moullin, Druitt, Keetley, and Gant; all these deservedly have their adherents. Both Heath and Pearce Gould have written useful little treatises on Surgical Diagnosis. Minor Surgery and Bandaging may be studied in the works of Heath or Caird and Cathcart.

The Science and Art of Surgery. By Sir J. E. ERICHSEN, F.R.S., LL.D. Tenth edition. Edited by the late MARCUS BECK, M.S., F.R.C.S., and RAYMOND JOHNSON, B.S., F.R.C.S. 1895. With nearly 1000 Wood Engravings. Two vols. 48*s.* London: Longmans, Green, and Co.

Manual of Surgery for Students. By Professor W. ROSE, F.R.C.S., and ALBERT CARLESS, F.R.C.S. Pp. 1160 and 400 Illustrations. 21*s.* London: Baillière, Tindall, and Cox.—This is the latest book published on surgery and we have been able to highly commend it in our columns.

Surgery: its Theory and Practice. By W. J. WALSHAM, F.R.C.S., &c. Sixth edition. With 410 Engravings. 12*s.* 6*d.* London: J. & A. Churchill.

Outlines of Practical Surgery. By WALTER G. SPENCER, M.B., M.S., F.R.C.S. 1898. Pp. 694. Price 12*s.* 6*d.* net. London: Baillière, Tindall, and Cox.

A System of Surgery. Edited by FREDERICK TREVES, F.R.C.S. 1895. Two vols. With four Coloured Plates and several hundred original Illustrations. 48*s.* London: Cassell and Co.

A System of Surgery. Edited by TIMOTHY HOLMES, F.R.C.S., and J. W. HULKE, F.R.C.S., F.R.S. Third edition. Three vols. With Coloured Plates and numerous Illustrations. Price £4 4*s.* London: Longmans, Green, and Co.

Dictionary of Practical Surgery. Edited by C. HEATH, F.R.C.S. Third edition. 1889. Two vols. Vol. I., pp. 978; Vol. II., pp. 884. 32*s.* London: Smith, Elder, and Co.

Surgery. By C. W. MANSELL MOULLIN, F.R.C.S. 1891. With 497 Engravings. 34*s.* London: J. & A. Churchill.

Manual of Practice of Surgery. Two vols. By T. BRYANT, M.D., F.R.C.S. Fourth edition. With 750 Engravings. 32*s.* London: J. & A. Churchill.

Manual of Surgery. By F. TREVES, F.R.C.S. 1894. Pp. 574. Three vols. 22*s.* 6*d.* London: Cassell and Co.

Druitt's Surgeon's Vade-Mecum. Edited by STANLEY BOYD, F.R.C.S. Twelfth edition. With 373 Engravings. London: J. & A. Churchill.

Index of Surgery. By C. R. B. KEETLEY, F.R.C.S., &c. Fourth edition. 1887. Pp. 526. 10*s.* 6*d.* London: Smith, Elder, and Co.

Operative Surgery. By F. TREVES, F.R.C.S. 1894. Pp. 1550. 42*s.* London: Cassell and Co.

Students' Handbook of Surgical Operations. By F. TREVES, F.R.C.S. 7*s.* 6*d.* 94 Illustrations. London: Cassell and Co.

The Operations of Surgery. By W. H. A. JACOBSON, F.R.C.S. Third edition. 34*s.* London: J. & A. Churchill.

Manual of Operative Surgery. By H. J. WARING, M.S., M.B., B.Sc., F.R.C.S. 1898. Pp. 661. Edinburgh and London: Young J. Pentland.

Senn: Principles of Surgery. By N. SENN, M.D., Ph.D. Second edition. One vol., Pp. 656. With 178 fine Wood Engravings and Coloured Plates. 24*s.* 6*d.* London: The Rebman Publishing Company.

Digitized by Google

The Science and Practice of Surgery: a Complete Text-book. By F. J. GANT, F.R.C.S., Senior Surgeon, Royal Free Hospital. Third edition, about 1100 Engravings. Two vols. Price 36*s.*

Guide to Surgical Diagnosis. By C. HEATH, F.R.C.S. Second edition. 6*s.* 6*d.* London: J. & A. Churchill.

Elements of Surgical Diagnosis. By A. P. GOULD, F.R.C.S., &c. Pp. 584. 7*s.* 6*d.* London: Cassell and Co.

Minor Surgery and Bandaging. By C. HEATH, F.R.C.S. Eleventh edition. With 176 Engravings. 6*s.*

A Surgical Handbook. By CAIRD and CATHCART. With Illustrations. Eighth edition. 1897. 8*s.* 6*d.* London: Griffin and Co.

A Text-book of Surgery. Edited by WILLIAM W. KEEN, M.D., LL.D., and J. WILLIAM WHITE, M.D., Ph.D. Third edition. In two parts. Profusely illustrated with Coloured and Black and White Plates. Price 42*s.* London: The Rebman Publishing Company.

Surgical Handicraft: A Manual of Surgical Manipulations and Minor Surgery for the use of General Practitioners, House Surgeons, Students, and General Dressers. By WALTER PYE, F.R.C.S. Revised and Edited by T. H. R. CROWLE, F.R.C.S. Third Edition. 1891. With 235 Engravings. 10*s.* 6*d.* Bristol: John Wright and Co.

MIDWIFERY.

In this subject the student will find it advantageous to have two books; one a small and elementary work, which he can, if he likes, take with him when attending his cases; and the other a larger text-book, for systematic reading.

Of the elementary books we mention four:—

First Lines of Midwifery. By G. ERNEST HERMAN, M.B., F.R.C.P. 1897. 5*s.* London: Cassell and Co.—*Obstetric Aphorisms for Students.* By J. G. SWAYNE, M.D. Tenth edition. Fcap. 8vo, with Twenty Engravings. 3*s.* 6*d.* 1893. London: J. & A. Churchill.—*An Introduction to Midwifery.* By ARCHIBALD DONALD, M.D. Second Edition.—*A Short Practice of Midwifery.* By HENRY JELLETT, M.D. 6*s.* 1897. London: J. & A. Churchill.—All four are excellent for their purpose—that is, they serve well to instruct the student as to his practical duties and the points to be noted and watched in attending his first cases of labour. Dr. Swayne's book is the old-established favourite. The other two are more modern, but by any of the four the student will find himself much fortified.

General Text-books:—

A Manual of Midwifery. By A. L. GALABIN, M.D., F.R.C.P.—A very deservedly popular book; literally a manual as it is in one volume; clear and precise and sufficiently informatory to provide the student with all the information necessary for pass examinations. Fourth edition. Crown 8vo. 1897. With 271 Engravings. 15*s.* London: J. & A. Churchill.

A Handbook of Midwifery. By W. R. DAKIN, M.D., F.R.C.P. This new book is well suited to the student. It contains all the necessary information in a clear and precise manner and is illustrated by a number of most instructive drawings and diagrams. Large crown 8vo. 1897. With 400 Illustrations. Pp. 600. 18*s.* London: Longmans, Green, and Co.

The Student's Guide to the Practice of Midwifery. By D. LLOYD, M.D., F.R.C.P. Fourth edition. With two Coloured Plates and 226 Woodcuts. Fcap. 8vo. 10*s.* 6*d.*

The Science and Art of Midwifery. By W. T. LUSK, M.D.—This American work is undoubtedly in many ways the best English text-book on the subject. The amount of information contained is very large, the references complete, and the plan of the book is easy to follow. For honour examinations this book is a necessity. Fourth edition. 1892. Pp. 671. 18*s.* London: H. K. Lewis.

The Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D., F.R.C.P. Eighth edition. Two volumes, each containing 430 and 443 pages respectively.—This has long been a deservedly popular work with students. It practically held the field till the appearance of the two previous treatises, and is still, and we think fitly, the most widely read text-book on the subject. 1893. 28*s.* Ninth edition, ready this month. London: Smith, Elder, and Co.

The student will also find the following books of reference of use:—

Text-book of Midwifery. By the late OTTO SPIEGELBERG. Translated from the second German edition by Dr. HURRY.—This work in two volumes is published by the New Sydenham Society. Although a text-book in name it is not well adapted to the immediate needs of the student, who, however, may be advised to consult it on special points.

A Manual of Midwifery. By WILLIAM RADFORD DAKIN, M.D., F.R.C.P., Obstetrical Physician and Lecturer on Midwifery at St. George's Hospital, &c. With 393 Illustrations. 8vo, 18*s.* London: Longmans, Green, and Co.

An American Text-book of Obstetrics. NORRIS and DICKENSON. Two vols.—This work written by various authors will be found useful to refer to by the student or practitioner; it is profusely illustrated and contains a large amount of reliable information.

Difficult Labour. By G. ERNEST HERMAN, M.B., F.R.C.P. With 162 Illustrations. Price 12*s.* 6*d.*—This will also be found a useful work of reference on its subject.

Dührssen's Manual of Obstetric Practice. 6*s.* London: H. K. Lewis. 1897.—A useful compendium of German midwifery.

GYNÆCOLOGY.

A Manual of Gynæcology. By BERRY HART, M.D., and FREELAND BARBOUR, M.D.—The work consists of two parts and an appendix. Part I. deals with the Anatomy, Physiology, and Methods of Examination of the Female Pelvic Organs, and Part II. with the diseases peculiar to the organs. This favourite manual is especially strong in its anatomical and purely scientific sections, if somewhat less complete as a clinical guide. It has the advantage of giving at the end an Index of Recent Gynæcological Literature. Fifth edition. Pp. 722. 1897. Illustrated with Lithographs and 400 Woodcuts. London: W. & A. K. Johnston.

A System of Gynæcology. By many writers. Edited by THOS. CLIFFORD ALLBUTT, M.A., M.D., LL.D., F.R.C.P., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, Fellow of Gonville and Caius College; and W. S. PLAYFAIR, M.D., LL.D., F.R.C.P., Professor of Obstetric Medicine in King's College, and Obstetric Physician to King's College Hospital. Pp. 922. 1896. 25*s.*

Diseases of Women. By G. E. HERMAN, M.B., F.R.C.P.—This work contrasts with the preceding in being written mainly from the clinical point of view. It gives an exceedingly good and practical account of the subject and will no doubt become a widely read work with students and practitioners. Pp. 870. 1898. Large crown 8vo. With 252 Illustrations. London: Cassell and Co.

A Practical Text-book of the Diseases of Women. By ARTHUR H. N. LEWERS, M.D. — This is a smaller book, but like the above it treats the subject mainly from the clinical point of view. It is a deservedly popular work with students because of the extremely practical nature of its information. Fifth edition. 1897. Pp. 526. 10*s.* 6*d.* London: H. K. Lewis.

The Diseases of Women: a Concise Handbook for Students. By JOHN PHILLIPS, M.A., M.D., F.R.C.P. Second edition, revised and enlarged. With illustrations. 7*s.* 6*d.* London: Charles Griffin and Co., Limited.—Contains a great deal of information in a condensed form.

Diseases of Women. By J. C. WEBSTER, B.A., M.D., F.R.C.P. Edin.—This book can be recommended as containing all that a student will require to know without being unduly large. Crown 8vo. 1898. Pp. 678. 14*s.* London: Young J. Pentland.

The Diseases of Women. A Handbook for Students and Practitioners of Medicine. By J. BLAND SUTTON, F.R.C.S. Eng., and ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Edin. In one crown 8vo volume of 436 pages. With 115 Illustrations (mostly original) in the text. Cloth, forril back. Price 14*s.* London: The Rebman Publishing Company, Limited. 1897.

The following books of reference are recommended:—*Operative Gynæcology.* By HOWARD A. KELLY, M.D. 1898. Two vols. This book is most sumptuously illustrated, and is one of the most complete works on operative gynæcology in any language.—*A System of Gynæcology.* ALLBUTT and PLAYFAIR. 1896. As a work of reference, written as it is by many authors, this book will be found of great value, and gives a clear exposition of the views prevalent in this country at the present time.—*A Treatise on Gynæcology.* By S. POZZI, M.D. This work, in three volumes, is published by the New Sydenham Society, and while not well adapted for general reading will be found invaluable for reference. The same remark to a greater or less extent, applies to the following books:—*Diseases of the Ovaries.* By LAWSON TAIT, F.R.C.S. Fourth edition. 1883.—*Abdominal Surgery.* By J. GREIG SMITH. Sixth

Digitized by Google

edition.—*The Surgical Diseases of the Ovaries and Fallopian Tubes.* By J. BLAND SUTTON, F.R.C.S. New and enlarged edition, with 146 Illustrations. Price 21*s.*—*The Diagnosis and Surgical Treatment of Abdominal Tumours.* By Sir SPENCER WELLS.—*Clinical Lectures on the Diseases of Women.* By J. MATTHEWS DUNCAN, M.D. Fourth edition.—*The Diseases of Women and their Treatment.* By H. MACNAUGHTON JONES, M.D., F.R.C.S.I., F.R.C.S.E. Seventh edition. 1894. Price 15*s.*

DISEASES OF CHILDREN.

It is only natural that students should be obliged by the medical schools to give some attention to the study of the diseases of children when it is considered that in general practice one patient at least out of every three will be a child. At present some of the examining boards, as the Royal University of Ireland, require candidates for the M.B. degree to produce certificates of having attended a practical course on the diseases of children, and the students are also specially examined in this subject. We therefore suggest for their guidance the following text-books:—*Diseases of Children, Medical and Surgical.* By HENRY ASHBY, M.D., F.R.C.P., and G. A. WRIGHT, B.A., M.B., F.R.C.S. Eng. Enlarged and improved edition, with 192 Illustrations. 8vo. Pp. 248. 25*s.* London: Longmans, Green, and Co. This admirable work, as it deals with diseases of children from both a medical and surgical point of view, can be recommended to students as containing everything that they will require to know.—*The Diseases of Children.* By JAMES F. GOODHART, M.D., F.R.C.P. Fifth edition. 10*s.* 6*d.* London: J. & A. Churchill. For those who want to study diseases of children from a medical aspect we can recommend this most popular manual, written, as it is, by one who convinces the reader that he has seen everything he describes. A new edition is nearly ready.—*The Diseases of Children (Medical).* By H. BRYAN DONKIN M.D., F.R.C.P. Medium 8vo. 16*s.* London: Charles Griffin and Co. This is in many respects a most original book.—*Clinical Examination and Treatment of Sick Children.* By JOHN THOMSON, M.D. Edinburgh: W. F. Clay.—For those students who desire to know the surgical aspect of the affections of children there are two useful text-books—*Surgical Diseases of Children,* by E. OWEN, M.B., F.R.C.S. Eng., third edition, revised and enlarged, with Chromo Plates and Engravings, price 21*s.*, Cassell and Co., Limited, London, Paris, and New York; and *The Surgical Diseases of Children and their Treatment by Modern Methods,* by D'ARCY POWER, M.A., M.B. Oxon., F.R.C.S. Eng., crown 8vo, price 10*s.* 6*d.* London: H. K. Lewis.—The following larger works are recommended for reference:—EUSTACE SMITH'S *Treatise on Disease in Children.* Second edition. Price 22*s.* 1889. 8vo. Pp. 895. London: J. & A. Churchill.—*The Diseases and Infancy and Childhood.* By L. EMMETT HOLT, A.M., M.D. Pp. 1117. Price 25*s.* London: Henry Kimpton. 1897. *Lectures on Children's Diseases.* By HENOCH. Two vols. Translated by JOHN THOMSON, M.D., F.R.C.P. Ed., from the fourth German edition. This treatise is published by the New Sydenham Society.—*Diseases of Children.* Edited by LOUIS STARR, M.D., and sixty Associates. Two vols. Price 42*s.* London: The Rebman Publishing Co. This is one of the most recent large works on diseases of children compiled in America. It is well got up and profusely illustrated.—*Medical Diseases of Infancy and Childhood.* By DAWSON WILLIAMS, M.D. Lond. 648 pages, with 52 Illustrations. 10*s.* 6*d.* London: Cassell and Co.—*Pediatrics: The Hygienic and Medical Treatment of Diseases in Children.* By THOMAS MORGAN ROTCH, M.D., Professor of Diseases of Children, Harvard University. Two vols. Pp. 1124. Price 25*s.* net. Edinburgh and London: Young J. Pentland.—Two other very useful books are those of Dr. CHEADLE: *On the Principles and Exact Conditions to be Observed in the Artificial Feeding of Infants* (London: Smith, Elder, and Co., Fourth edition, price 5*s.*), and Dr. LOUIS STARR: *Hygiene of the Nursery* (Sixth edition, crown 8vo, 3*s.* 6*d.* London: H. K. Lewis).

On the Natural and Artificial Methods of Feeding Infants and Young Children. By EDMUND CAUTLEY, M.D., Physician to the Belgrave Hospital for Children. Crown 8vo, 7*s.* 6*d.* London: J. & A. Churchill.

OPHTHALMOLOGY.

Either of the two following handbooks on Ophthalmology will be found to contain all that is necessary to the student of medicine who has no inclination to make a special study of the subject.

Handbook of Diseases of the Eye. By HENRY R. SWANZY, M.B., F.R.C.S.I. Sixth edition. Pp. 608. 1897. An excellent book. Price 12*s.* 6*d.* London: H. K. Lewis.

Nettleship's Diseases of the Eye. Edited by T. HOLMES SPICER, F.R.C.S. Sixth edition. Student's Guide Series. Price 8*s.* 6*d.* Fcap. 8vo. London: J. & A. Churchill.

By those who wish for fuller information on the subject the larger text-books must be consulted, of which, perhaps, *The Text-book of Ophthalmology,* by Professor FUCHS, of the Vienna University, is the most generally useful. This has been recently translated from the German into English by A. DUANE, and is published in one large octavo volume, with 178 Illustrations, price 21*s.*, by H. K. Lewis.

Most students find the study of errors of refraction difficult and unattractive and are consequently inclined to neglect this important branch of the subject. *The Manual for Students on the Refraction of the Eye,* by GUSTAVUS HARTRIDGE, is a most useful little book, as it explains simply the principles on which are based the methods in use in the out-patient department.

It is unnecessary, and, indeed, undesirable, here to enumerate all the text-books which have been written on diseases of the eye, but the following may be mentioned as generally useful books:—

The Diseases and Injuries of the Eye. By W. H. H. JESSOP, M.A., F.R.C.S., Ophthalmic Surgeon to St. Bartholomew's Hospital. With Engravings. London: J. & A. Churchill.

Diseases of the Eye. By GEORGE BERRY, M.B., F.R.C.S. Edin. Price 25*s.* Edinburgh and London: Young J. Pentland.

Handbook of Ophthalmic Science and Practice. By HENRY JULER, F.R.C.S Second edition.

The Fundus Oculi. By W. ADAMS FROST, F.R.C.S. An excellent book with admirable illustrations. Price £3 3*s.* Edinburgh and London: Young J. Pentland.

The Refraction of the Eye. A manual for students. By GUSTAVUS HARTRIDGE, F.R.C.S., Surgeon to the Royal Westminster Ophthalmic Hospital. Ninth edition. With 100 Illustrations, test types, &c. Crown 8vo. 1896. 6*s.*

The Ophthalmoscope. A manual for students. Third edition. With 4 Coloured Plates and 67 Engravings. Crown 8vo, 4*s.* 6*d.* London: J. & A. Churchill.

The Refraction of the Eye. By A. STANFORD MORTON, F.R.C.S. Sixth edition. 1897. 3*s.* 6*d.* London: H. K. Lewis.

To those who are conversant with French the "Traité Complet d'Opthalmologie," by L. DE WECKER and E. LANDOLT, may be recommended as the most valuable work of reference. It is published in four large volumes at a price of about 20 francs each volume, and is consequently scarcely adapted for the student's use. A German edition of this work may also be obtained.

PATHOLOGY.

Manual of General Pathology. By JOSEPH FRANK PAYNE, M.D. Oxon., F.R.C.P. Pp. 702. 150 Illustrations.—Deals specially with general pathology and pathological anatomy and the processes and causes of disease, including parasites, both animal and vegetable. Special pathology and pathological histology are not touched upon, but on general pathology it is one of the best books in the language. London: Smith, Elder, and Co. 1888.

A Text-book of Pathology, Systematic and Practical. By Professor D. J. HAMILTON.—An admirably original, but somewhat unequal work. The most complete and systematic work published in the English language. Contains a very full and accurate bibliography. Invaluable for reference and for study for the higher examinations. Published in two volumes (the second volume is divided into two parts), which may be bought separately. Vol. I. (London: Macmillan and Co., 1889, pp. 736, 225 Illustrations, woodcuts, and coloured lithographs, price 21*s.* net) deals with the technique of the post-mortem room and the histological and bacteriological laboratories. An account is also given of the general pathological processes of the diseases of the blood, the heart and blood-vessels, and of tumours. Vol II., 1895, Part 1 (172 Illustrations, pp. 514, price 15*s.* net), treats of diseases of the air-passages and lungs, of the liver, of the genito-urinary appartus, and the alimentary tract, except the intestines, whilst Part 2 of Vol. II. (225 Illustrations, pp. 624, price 15*s.* net) completes the description of the diseases of

Digitized by Google

the alimentary tract and then takes up in turn the nervous system (very good), diseases of the mamma, bones and joints, the skin, malformations, diseases of the fœtal membranes and placenta, vegetable and animal parasites, animal heat and fever.

A Text-book of Special Pathological Anatomy. By ERNST ZIEGLER. Translated and edited from the eighth German edition by DONALD MACALISTER, M.A., M.D., and HENRY W. CATTELL, M.A., M.D. Sections I.—VIII. 17*s.* net. Sections IX.—XV. 17*s.* net. The Alimentary Tract; the Liver and Pancreas; the Respiratory System; the Urinary Organs; the Genital System; the Eye; the Ear. 1896. London: Macmillan and Co.—A first instalment of a new English edition of a leading text-book notable for its excellent and abundant illustrations and full references to literature. A good text-book for the higher examinations. The subjects treated in this volume embrace the Blood and Organs of Circulation, the Osseous and Nervous Systems. The complete work (published by Fischer, of Jena) comprises a volume on General Pathological Anatomy, as well as the whole of Special Pathological Anatomy, of which the present volume constitutes about one-half.

A Manual of General Pathology for Students and Practitioners. By WALTER SYDNEY LAZARUS-BARLOW, B.A., M.D., late Demonstrator of Pathology, and Examiner in Sanitary Science in the University of Cambridge. 8vo. 21*s.* London: J. & A. Churchill.

A Manual of Pathology. By JOSEPH COATS, M.D. Pp. 1180. Numerous Illustrations. London: Longmans, Green, and Co. Third edition. 1895. 31*s.* 6*d.*—An interesting treatise on morbid anatomy and pathology; covers a great deal of ground; in most cases very reliable and a good text-book, especially for the student preparing for the higher examinations.

Practical Pathology. By GERMAN SIMS WOODHEAD, M.D., F.R.S.E. Third edition. 1892. Pp. 652. With 195 Coloured Plates from Original Drawings.—This book is almost an essential to the proper study of the subject. It is not only thoroughly clear and well arranged, but beautifully illustrated. The points where the student might be expected to be most in difficulty have received special attention. 25*s.* Edinburgh and London: Young J. Pentland.

An Introduction to Pathology and General Morbid Anatomy. By T. HENRY GREEN, M.D., F.R.C.P. Revised and enlarged by H. MONTAGUE MURRAY, M.D., F.R.C.P. 224 Engravings.—An excellent *résumé* of pathology from the student's point of view. Brought well up to date, especially in the sections dealing with inflammation, the specific infectious fevers, and the nervous system. May be confidently recommended as giving a very good and accurate account of the groundwork of pathology and as containing sufficient information to enable the student to pass any ordinary examination on the subject. Price 17*s.* London: Henry Renshaw.

Text-book of General Pathology and Pathological Anatomy. By Professor THOMA. Translated from the German by ALEXANDER BRUCE, M.A., M.D., F.R.C.P.E., F.R.C.S.E., Vol. I., with 436 Illustrations. London: Adam and Charles Black. 1896.—An admirable work for reference. Professor Thoma treats in this first volume of the natural history of disease, pays special attention to the questions of heredity and malformations, to the physics and mathematics of the laws of pathology, especially of the circulatory system.

A Text-book of Morbid Histology for Students and Practitioners. By RUBERT BOYCE, M.B., M.R.C.S. Pp. 477, with 130 Coloured Photographic Illustrations. 31*s.* 6*d.* London: H. K. Lewis. 1892.—Contains good descriptions of morbid histological specimens; also a number of photographs, which, however, are of very unequal merit and value. Exceedingly useful for the advanced student and the laboratory worker. A carefully selected bibliography is appended.

The Elements of Pathological Histology. By A. WEICHSELBAUM. Translated by W. R. DAWSON, M.D. 21*s.* net. 1895. London: Longmans, Green, and Co.—A work of approved merit, concise and clear in exposition; useful for practical study, and admirably illustrated.

A Manual of General Pathology. By WALTER S. LAZARUS-BARLOW. London: J. & A. Churchill. 1898. Price 21*s.*—A work of considerable merit, which should prove most useful to the student of latter-day pathology.

The following books have different uses for students which we have tried to briefly indicate:—

Practical Pathology. By JOHN LINDSAY STEVEN, M.D. Pp. 266. 7*s.* 6*d.* Glasgow: James Maclehose and Sons. 1887.—A concise and well-arranged description of methods and of pathological anatomy and histology. There are no illustrations, but the descriptions are clear and concise. Useful for a student going in for examination or as a supplement to demonstrations.

Practical Pathology and Morbid Histology. By HENEAGE GIBBES, M.D. Pp. 320. Illustrated with 60 Photographic Reproductions. Edinburgh and London: Young J. Pentland. 1891.—A good practical book with a series of photographs of typical pathological microscopic specimens. Useful for private laboratory work rather than for examination purposes.

Surgical Pathology and Morbid Anatomy. By ANTHONY BOWLBY, F.R.C.S. Third edition. London: J. & A. Churchill.—A capital little handbook on surgical pathology. Well up to date as regards pathogenesis.

Elements of Surgical Pathology. By AUGUSTUS J. PEPPER, M.S., M.B. Lond., F.R.C.S. Eng. Pp. 532. 99 Engravings. Fourth edition, re-written and enlarged. 8*s.* 6*d.* London, Paris, and Melbourne: Cassell and Co., Limited. 1894.—A compact little handbook of surgical pathology.

A Handbook of Surgical Pathology. By W. J. WALSHAM, M.B., F.R.C.S. Eng.; and D'ARCY POWER, M.A., M.B. Oxon., F.R.C.S. Eng. Pp. 634. London: Baillière, Tindall, and Cox. Second edition. 1890. Price 7*s.* 6*d.*—A clear and concise description of the specimens in the Museum of St. Bartholomew's Hospital, and therefore specially useful to students of that school or to those that have access to that museum. But the descriptions are so good that this work will serve as a capital text-book to any student preparing for an examination in surgical pathology.

Pathological Anatomy of Diseases. By NORMAN MOORE, M.D. London: J. & A. Churchill. Fcap. 8vo. 8*s.* 6*d.*—An accurate and concise, but not very full, student's manual of morbid anatomy of 416 pages, with 110 figures.

Practical Morbid Anatomy. By H. D. ROLLESTON, M.A., M.D., F.R.C.P.; and A. A. KANTHACK, M.D., M.R.C.P. Cambridge University Press and H. K. Lewis. Price 6*s.* 1894. Pp. 240.—A capital account of the methods and course of procedure to be adopted in the post-mortem room. Practical, but thoroughly scientific throughout.

Section Cutting and Staining. By WALTER S. COLMAN, M.B. Lond. London: H. K. Lewis. Second edition, just ready.—A handy little guide to the preparation of normal and morbid histological specimens. Concise, and gives everything that is really necessary for ordinary class work.

Post-Mortem Examinations in Medico-Legal and Ordinary Cases. With Special Chapters on the Legal Aspects of Post Mortems and on Certificates of Death. By J. JACKSON CLARKE, M.B.Lond., F.R.C.S. Fcp. 8vo. 2*s.* 6*d.* London: Longmans, Green, and Co. 1898.

Atlas and Essentials of Pathological Anatomy. By Professor C. BOLLINGER. With 112 Coloured Plates. Two vols. 12*s.* 6*d.* net each. 1898. London: Baillière, Tindall, & Cox.

The following books are hardly to be used as text-books, but for one reason or another the student will do well to supplement his reading by consulting them:—

Lectures on Surgical Pathology. By Sir JAMES PAGET, Bart., F.R.S., &c. Revised and edited by Professor WM. TURNER, F.R.S. Pp. 844. 130 Illustrations. 21*s.* London: Longmans, Green, and Co. 1876. Fourth edition.—Still one of the most valuable books of reference on surgical pathology in our language, and should be read by every student as a model on which to base methods of observation and study.

An Introduction to General Pathology. By JOHN BLAND SUTTON, F.R.C.S. 14*s.* London: J. & A. Churchill.—An admirable introduction to the subject of evolution in pathology, well worth study by those who wish to gain more than a mere examination knowledge of the subject.

Lectures on Pathological Anatomy. By Sir SAMUEL WILKS, Bart., M.D., F.R.S., and the late WALTER MOXON, M.D., F.R.C.P. Third edition, thoroughly revised by Sir SAMUEL WILKS, M.D., Bart., LL.D., F.R.S. 18*s.* London and New York: Longmans, Green, and Co. 1889.—An admirable description of macroscopic morbid anatomy, doing for medicine what Paget's lectures have done for surgery. May be studied with advantage both before and after practical work is engaged in.

Digitized by Google

BACTERIOLOGY.

The following works will be found useful to students either for examination purposes or for special study.

Ptomaines, Leucomaines, Toxins, and Antitoxins. By Professor VICTOR C. VAUGHAN, Ph.D., M.D.; and Associate Professor FREDERICK G. NOVY, Sc.D., M.D. Third edition. Revised and enlarged. Philadelphia: Lea Brothers and Co. 1896. Pp. 604. $3.—The best book in the language on bacterial products and poisons. Well up to date as regards methods.

Manual of Bacteriology. By ROBERT MUIR, M.A., M.D., F.R.C.P. Edin., and JAMES RITCHIE, M.A., M.D., B.Sc. Edinburgh and London: Young J. Pentland. 1897.—An exceedingly good text-book for the medical student. Methods, descriptions, and illustrations alike excellent. The principles of bacteriology are well set forth. A most useful list of literature is appended. Well up to date in all respects.

Elementary Practical Bacteriology, including Bacteriological Analysis and Chemistry. By A. A. KANTHACK, M.D., M.R.C.P., and J. H. DRYSDALE, M.B., M.R.C.P. London: Macmillan and Co. 1896. Pp. 180. Sixteen Woodcuts. Price 4*s.* 6*d.*—A guide to the elementary study of bacteriology. The work deals in turn with general and special methods of cultivation and examination of micro-organisms, with the more important species of bacteria, and with bacteriological analysis and bacteriological chemistry.

Micro-organisms and Disease. An Introduction to the Study of Specific Micro-organisms. By E. KLEIN, M.D., F.R.S. Fourth edition. Revised. Pp. 595, with 20 Illustrations. Price 10*s.* 6*d.* London: Macmillan and Co., Ltd. 1896.—A standard text-book.

Practical Guide to the Demonstration of Bacteria in the Animal Tissues. By Dr. H. KÜHNE. Translated and edited by VINCENT DORMER HARRIS, M.D., F.R.C.P. London: Baillière, Tindall, and Cox. 1890. Pp. 53. Figs. 7. 2*s.* 6*d.*—A practical little handbook.

Applied Bacteriology. By T. H. PEARMAIN and C. G. MOOR. London: Baillière, Tindall, and Cox. Second Edition. 1898. Price 12*s.* 6*d.* net.—A lucid exposition of bacteriology, especially as it relates to the work of the medical officer of health and to the student preparing himself for such work.

Medical Microscopy. By FRANK J. WETHERED, M.D., F.R.C.P. London: H. K. Lewis. 1891. Pp. 250. 40 Illustrations. Price 9*s.*—A guide to the preparation of microscopical preparations and examination of sputum, urine, &c. Useful for advanced students and general practitioners.

Bacteriological Technology for Physicians. By Professor C. J. SALOMONSEN. Translated by WILLIAM TRELEASE. Pp. 162, with 72 Figures in the text. New York: William Wood and Co. 1890.—A most concise and accurate work on methods, well adapted to the use of the student, as the apparatus described as necessary is both simple and inexpensive.

Manual of Bacteriology for Practitioners and Students. With especial reference to Practical Methods. By Professor S. L. SCHENK. Translated by W. R. DAWSON, B.A., M.D. With an Appendix by the Translator. 100 Illustrations, partly coloured. 10*s.* net. London and New York: Longmans, Green, and Co. 1893.—A really good student's text-book.

The Principles of Bacteriology: a Practical Manual for Students and Physicians. By A. C. ABBOTT, M.D. Fourth Edition. 1898. With Illustrations.—A very good manual for the student who wishes to study the technique of bacteriological investigation.

Studies on Fermentation. By L. PASTEUR. Translation, with Notes, Index, and original Illustrations, by FRANK FAULKNER and D. CONSTABLE ROBB, B.A. London: Macmillan and Co. 21*s.* 1879. Pp. 418, with 12 Plates and 85 Figures in text.—An admirable work and one that should be read by every advanced student of bacteriology.

On Fermentation. By P. SCHÜTZENBERGER. Fourth edition. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 1891. Pp. 331, with 28 Illustrations. Price 5*s* (Vol. XX., International Scientific Series.)—A capital *résumé* of the subject for advanced students.

Technical Mycology. By Prof. FRANZ LAFAR. Translated by CHARLES T. C. SALTZER. In Two Volumes. Vol. I: Schizomycetic Fermentation. Pp. 405. With Plates and 90 Figures in the text. London: Charles Griffin and Co. Price 15*s.*—A valuable account of the processes of fermentation and fermentative processes.

Bacteria and their Products. By GERMAN SIMS WOODHEAD, M.D. 1891. Pp. 459, with 20 Photo-micrographs. London: Walter Scott. Price 3*s.* 6*d.*—Gives a description of the more important micro-organisms and the diseases they produce and of fermentation; also a short history of bacteriology; includes an appendix dealing with bacteriological methods and with the classification and identification of micro-organisms. Is in every respect a first-class text-book, excellent in arrangement and clear and full in detail.

A Manual of Bacteriology. By GEORGE M. STERNBERG, M.D. New York: William Wood and Co. 1892.—A most complete and exhaustive work of 886 pages, of which over a hundred are devoted to bibliography. An encyclopædic, painstaking, and usually accurate *résumé* of the subject. Well illustrated with chromo-lithographic plates and 268 engravings. Too ponderous for the ordinary student, but very useful for the advanced worker. Dr. Sternberg has now issued a condensed text-book which is more suited to the general student of bacteriology.

A Text-book of Bacteriology for Students and Practitioners of Medicine. By G. M. STERNBERG, M.D., LL.D., Surgeon-General U.S. Army. Illustrated by 9 Heliotype and Chromo-lithographic Plates and 200 Engravings. 8vo. 24*s.* London: J. & A. Churchill.

Text-book of Bacteriology. By EDGAR M. CROOKSHANK, M.B. London: H. K. Lewis. 21*s.* net. Fourth edition, reconstructed, revised, and greatly enlarged.—A well-written and well-illustrated treatise on the subject. A good text-book, especially for those who have no opportunity of attending a practical course.

FORENSIC MEDICINE.

Manual of Medical Jurisprudence. By A. S. TAYLOR. Edited by T. STEVENSON, M.D. Crown 8vo. Twelfth edition. 1891. 56 Engravings. 14*s.* London: J. & A. Churchill.—An authoritative text-book.

Text-book of Forensic Medicine and Toxicology. By ARTHUR P. LUFF, M.D., B.Sc. Lond. Two vols. Pp. 416 and 360. 24*s.* With numerous Illustrations. London and New York: Longmans, Green, and Co.—This recently published work is one of the best on the subject.

Aids to Forensic Medicine and Toxicology. By WM. MURRELL, M.D., F.R.C.P. Price 2*s.* 6*d.* London: Baillière, Tindall, and Cox.

Principles of Forensic Medicine. By W. A. GUY and DAVID FERRIER, M.D., F.R.S. Seventh edition just published. 16*s.*—The work has been practically rewritten under the direction of Professor W. R. SMITH, M.D., F.R.S. Edin. London: Henry Renshaw.

Forensic Medicine and Toxicology. By J. DIXON MANN, M.D., F.R.C.P., Professor of Medical Jurisprudence and Toxicology, Owens College, Manchester; Examiner in Forensic Medicine, London University, and Victoria University, Manchester. Second edition, enlarged. 1898. 21*s.*

A System of Legal Medicine. By ALLAN MCLANE HAMILTON, M.D., Consulting Physician to the Insane Asylums of New York City, &c., and Mr. LAWRENCE GODKIN, of the New York Bar. Illustrated with 14 Coloured Plates and 161 Woodcuts and Half-tone Plate. Fully indexed by 3202 references. Royal 8vo. Two vols. Pp. 1400. 30*s.* per volume. Only sold in sets.

Poisons: their Effects and Detection. By ALEXANDER WYNTER BLYTH, M.R.C.S. Third edition. Revised and Enlarged. 1895. 21*s.* London: Chas. Griffin and Co.—A well-known work, much in esteem with toxicologists, partly as a book of reference, but chiefly as an excellent guide to the detection of poisons. The recent edition treats of the cadaveric alkaloids or ptomaines, and contains also a separate chapter on the connexion existing between the arrangement of the constituent parts of an organic molecule and physiological action.

Practical Toxicology for Physicians and Students. By Prof. RUDOLF KOBERT. Translated and edited by L. H. FRIEDBURG, Ph.D. New York: William R. Jenkins. 1897.—This work is full of useful information and contains an excellent series of tables of reactions of poisons, and is a valuable guide to the practical toxicologist.

A Text-book of Medical Jurisprudence for India. By J. B. LYON, F.C.S., F.I.C., Brigade-Surgeon, Bombay Medical Service; Chemical Analyser to Government; Professor of Chemistry and Medical Jurisprudence, Grant

Digitized by Google

Medical College, Bombay. Revised as to the Legal Matter by J. D. INVERARITY, of the Inner Temple, Barrister-at-Law, Calcutta. Bombay: Thacker, Spink, and Co. London: W. Thacker and Co., 87, Newgate-street. 1889.

The Principles and Practice of Medical Jurisprudence. By ALFRED S. TAYLOR, M.D., F.R.S., late Professor of Medical Jurisprudence to Guy's Hospital. Fourth Edition. By THOMAS STEVENSON, M.D., F.R.C.P. With 189 Engravings. Two vols. 8vo. 31*s.* 6*d.* London: J. & A. Churchill.

PUBLIC HEALTH.

Hygiene and Public Health. By B. ARTHUR WHITELEGGE, M.D., B.Sc. London: Cassell and Co. Price 7*s.* 6*d.*—This is an admirable text-book in every way. It is well fitted for the student of public health, and it possesses the additional advantage that it can be carried in the pocket.

The Elements of Vital Statistics. By ARTHUR NEWSHOLME, M.D. London: Swan Sonnenschein and Co.—A good standard text-book on vital statistics.

Knight's Annotated Model By-laws. London: Knight and Co. Price 12*s.*—This volume is almost essential for the student of public health.

Stratton's Public Health Acts. London: Knight and Co. Price 7*s.* 6*d.*—The Acts relating to public health arranged in a convenient form and with a useful index.

Public Health Laboratory Work. By HENRY R. KENWOOD, M.B. Edin., D.P.H. Second edition. London: H. K. Lewis. Price 10*s.* 6*d.*—An excellent little book for the laboratory bench. It is written for students preparing for the diploma of public health, and describes the processes of analysis of food, water, air, &c., with which he must have a practical acquaintance. It also includes an account by Professor Boyce of the methods employed in bacteriological research.

Notter and Firth's Theory and Practice of Hygiene. London: J. & A. Churchill. Price 18*s.*—A good and comprehensive text-book, founded largely on the late Dr. Parkes' "Hygiene."—Especially well-fitted for naval and military medical men.

A Simple Method of Water Analysis: especially designed for the Use of Medical Officers of Health. By JOHN C. THRESH, M.D., D.Sc., D.P.H. London: J. & A. Churchill. Price 2*s.* 6*d.*—This method may be carried out on the spot and gives valuable indications of the fitness or unfitness of water for drinking purposes.

Hygiene and Public Health. By LOUIS C. PARKES, M.D., D.P.H. Lond. Univ. Fifth edition. 10*s.* 6*d.* London: H. K. Lewis. 1897.—This edition has been thoroughly revised and brought up to date.

A Treatise on Hygiene and Public Health. Three vols. Edited by STEVENSON and MURPHY. London: J. & A. Churchill.—This is quite the standard work of reference at the present time. Vol. III. treats solely of sanitary law.

Hygiene (a Handbook of). By Surgeon-Major A. M. DAVIES, D.P.H. Camb. Pocket size, leather. With Illustrations. Price 12*s.* 6*d.* Griffin's "Pocket-Book" Series.—A comprehensive little work which should be in the hands of all who wish to qualify for the D.P.H. diplomas.

Manual of Public Health. By WYNTER BLYTH, M.R.C.S., L.S.A. London: Macmillan and Co. Price 17*s.* net.—An excellent manual dealing with general principles. It is fairly exhaustive and affords a good book of reference.

Water and Water-Supplies. By J. C. THRESH, D.Sc., M.D. Second edition. 8*s.* London: The Rebman Publishing Company, Limited.—A valuable dissertation on the important subject of water-supply. Besides practical details of the finding of water and the construction of wells, it contains also admirable chapters on the quality of water and the value of chemical and bacteriological analysis in enabling an opinion to be given upon it.

Final Report of the Royal Commission on Vaccination. Eyre and Spottiswoode. Price 1*s.* 10*d.*

MEDICAL ELECTRICITY.

Medical Electricity: A Practical Handbook for Students and Practitioners.—By H. LEWIS JONES, M.A., M.D., F.R.C.P. Second edition. With Illustrations. Crown 8vo. 10*s.* 6*d.* Pp. 454. 101 Figures in text. London: H. K. Lewis.—*A Manual of Practical Medical Electricity.*—By DAWSON TURNER, B.A., M.D., F.R.C.P. Edin. Second edition. London: Baillière, Tindall, and Cox. 1897.—The student who wishes to become acquainted with this subject cannot do better than begin by reading one or other of these excellent books. Of course they do not pretend to go so fully into the subject as Erb's Treatise in Von Ziemssen's "Handbook of General Therapeutics," or Bigelow's "International System of Electro-Therapeutics," or Rockwell's "Medical and Surgical Uses of Electricity"; but as thoroughly practical guides to electrical diagnosis, the choice, preservation, and use of electrical apparatus for medical purposes, and the methods of application they are the best books on the subject with which we are acquainted. Certain illustrations, reproduced from photographs, of patients with paralysis of particular muscles or groups of muscles are a most useful feature in Dr. Jones's book. Dr. Turner's work being the more recent contains a chapter on the x rays.

The Roentgen Rays in Medical Work.—By DAVID WALSH, M.D. Edin. London: Baillière, Tindall and Cox. 1897. Price 6*s.*—An excellent little volume on the subject in its application to medical work.

DENTAL.

A System of Dental Surgery. By the late Sir JOHN TOMES, F.R.S. Fourth edition. Edited by CHARLES S. TOMES, M.A., F.R.S. Crown 8vo, 289 Engravings. 16*s.* London: J. & A. Churchill.

Diseases and Injuries of the Teeth. By MORTON SMALE and J. F. COLYER. With 334 Illustrations. Large crown 8vo. 15*s.* London: Longmans, Green and Co.

Dental Anatomy, Human and Comparative. By CHARLES S. TOMES. Fifth edition. Crown 8vo., 235 Engravings. London: J. & A. Churchill.

A Practical Treatise on Mechanical Dentistry. By RICHARDSON. Seventh edition. Edited by GEO. WARREN. London: J. & A. Churchill.

Dental Materia Medica and Pharmacology. By CHARLES W. GLASSINGTON. London: J. & A. Churchill.

A Manual on Dental Metallurgy. By ERNEST A. SMITH. London: J. & A. Churchill.

MISCELLANEOUS.

The Anatomy of the Nasal Cavity and its Accessory Sinuses. By Dr. A. ONODI, Lecturer on Rhino-Laryngology in the University of Budapest. An atlas for practitioners and students, translated by ST. CLAIR THOMSON, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond. Plates, small 4to. 6*s.* net. London: H. K. Lewis.

Elements of Practical Pharmacy and Dispensing: Intended for Students of Medicine. By W. ELBORNE, B.A. Cantab., F.L.S., F.C.S. Extra crown 8vo, with Litho-plates and numerous Illustrations, cloth. 8*s.* 6*d.* London: Charles Griffin and Co.—A practical little book containing a Chemical Pharmacy and Laboratory Course, a Galenical Pharmacy and Laboratory Course, and a Practical Course of Dispensing, with Facsimiles of Autograph Prescriptions.

The Student's Guide to Diseases of the Chest, including the Principal Affections of the Pleuræ, Lungs, Pericardium, Heart, and Aorta. By VINCENT D. HARRIS, M.D., F.R.C.P., Physician to the Victoria Park Hospital for Diseases of the Chest. With 55 Engravings. Pp. 419. Fcap. 8vo. 7*s.* 6*d.* London: J. & A. Churchill.

Text-book of Diseases of the Ear and Adjacent Organs. By Professor POLITZER, of Vienna. Translated from the third German edition by OSCAR DODD, M.D., and edited by Sir WM. DALBY, B.A., M.B., F.R.C.S. Profusely illustrated. Price 21*s.* London: Baillière, Tindall, and Cox.—A reliable book, and contains all that is known on the subject.

Diseases of the Ear. Including the Anatomy and Physiology of the Organ, together with the treatment of the affections of the Nose and Pharynx which conduce to Aural Disease (a Treatise). By T. MARK HOVELL, F.R.C.S.E., M.R.C.S., Aural Surgeon to the London Hospital and Lecturer on Diseases of the Throat in the College, &c. 8vo, with 122 Engravings. 18*s.* 1894. London: J. & A. Churchill.

Practical Plant Physiology. By Dr. W. DETTMER. Translated from the Second German Edition by S. A. MOOR, M.A., F.L.S. Illustrated. London: Swan Sonnenschein and Co. 1898. Price 12*s.*—Recently reviewed in our columns. An experimental book appealing on the whole to research students, but "it would prove useful in the hands of a capable demonstrator in the biological classes."

Manual of Botany. Vol. I., Morphology and Anatomy. By J. REYNOLDS GREEN, Sc.D., M.A., F.R.S., Professor of Botany to the Pharmaceutical Society. Crown 8vo, with

about 778 Engravings. 7s. 6d. 1897. Vol. II., Classification and Physiology. 415 Engravings. 10s. London: J. & A. Churchill.

Diseases of the Skin. By W. A. JAMIESON, M.D., F.R.C.P. Edin. A Manual for Students and Practitioners. Fourth edition, revised and enlarged, 8vo, cloth, pp. xvi.-676, with coloured Illustrations. 1894. Price 21s. (Pentland's Medical Series, Vol. I.)

Diseases of the Throat, Nose, and Ear. By P. MCBRIDE, M.D., F.R.C.P. Edin. Second edition, revised and enlarged, 8vo, cloth, pp. xvi.-632, with Coloured Illustrations from original drawings. 1894. Price 25s. (Pentland's Medical Series, Vol. III.)

Dictionary of Medicine, Biology, and Allied Sciences. Illustrated By G. M. GOULD, A.M., M.D. Price 40s. London: Baillière, Tindall, and Cox.—This is the best dictionary of medical terms we have seen. It should find a place in the library of every medical man.

Outlines of Zoology. By THOMSON J. ARTHUR, M.A. Second edition, revised and enlarged, with 266 Illustrations in the text. Price 15s. Edinburgh: Young J. Pentland.

Clinical Lectures on Mental Diseases. By J. S. CLOUSTON, M.D., F.R.C.P. Edin. Fourth edition. With 15 Plates, crown 8vo. 14s. London: J. & A. Churchill.

The Student's Medical Dictionary. By G. M. GOULD, A.M., M.D. Tenth edition. 14s. net. London: H. K. Lewis.

A Pocket Medical Dictionary. By the same Author. 2s. 6d. net. London: H. K. Lewis.

POST-GRADUATE COURSES.

THE LONDON POST-GRADUATE COURSE.—This course is specially arranged to meet the wants of the practitioner and to enable him during his leisure time to brush up his knowledge on subjects about which he may desire further information. It has been both popular and successful and has been attended by men from all parts of the Empire, from all branches of the Services, from the United States of America, as well as from foreign countries. Members can enter for each or all of the courses of lectures for the term, for half the term, or for all the lectures for one week, and thus each can obtain just what he wants and in the shortest possible time. The Vacation Courses have been attended by large numbers of practitioners and have been much appreciated. By this means men who wished to bring themselves abreast of the scientific knowledge of the day have been able to learn the elements of the technique of bacteriology and the latest advances in hygiene in a fortnight's daily course. The staffs of the following hospitals have associated themselves for teaching purposes — viz., the Hospital for Diseases of the Skin, Blackfriars; the London Throat Hospital; and the Bethlem Royal Hospital for Lunatics; and courses are given at the Bacteriological Laboratory, King's College, at the Parkes Museum on Hygiene, and at the Cleveland-street Sick Asylum on Clinical Medicine and Surgery. The fees are £1 1s., £2 2s., and £3 3s., according to the number of lectures in the course. Further information can be obtained from, and fees should be paid to, Dr. Fletcher Little, Secretary, 32, Harley-street, Cavendish-square, W.

CHARING-CROSS HOSPITAL.—Special series of clinical lectures and practical demonstrations, exclusively arranged for the convenience of practitioners, are given at the hospital by members of the staff throughout the year. The lectures for the year are arranged in three courses, each course consisting of ten meetings and lasting ten weeks. Two of these courses are held during the winter and one during the summer. The class meets on each Thursday afternoon at 4 P.M. in the board-room of the hospital, and proceeds thence to the wards or other department in which the demonstration may be held. Practitioners wishing to join the class can receive any further information as to the dates and subjects by communicating with the Honorary Secretary or the Honorary Treasurer at the hospital.

WEST LONDON HOSPITAL.—This hospital is using the excellent opportunities afforded it by its position as the general hospital for Hammersmith and a populous surrounding neighbourhood to offer similar post-graduate instruction to members of the medical profession. All communications from those desirous of joining the classes should be addressed to Mr. L. A. Bidwell, Dean of the Hospital.

Medical News.

THE MEDICINAL SUPPLIES OF POOR-LAW UNIONS IN IRELAND.—A circular has been sent by the Local Government Board to all boards of guardians in Ireland calling their attention to the issue of a new edition of the British Pharmacopœia and to the fact that contractors of medicine are obliged by the terms of their bond to supply all drugs in accordance with the standard prescribed by the latest edition of the Pharmacopœia.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next examination for certificates in nursing and attending the insane will be held on Monday, Nov. 7th, 1898. Candidates should obtain from the Registrar (Dr. Spence, Burntwood Asylum, near Lichfield) a schedule to be filled up, signed, and returned to him at least four weeks before the date of the examination. Monday, Oct. 10th, will be the last day upon which, according to the rules, candidates can enter their names for the November examination.

THE SANITARY INSTITUTE CONGRESS. — The programme of the local arrangements for the Congress at Birmingham is now complete. The opening will be on Sept. 27th and the ending on Oct. 1st. The general reception is to be held in the Town-hall, the conferences and sections at Mason College. The president's inaugural address and the popular lecture will be delivered in the large lecture theatre of the Midland Institute, Sir Joseph Fayrer presiding. The Lady Mayoress (Mrs. Beale) is to preside over the section of Domestic Hygiene. Mr. W. Henman is president of Section II. on Engineering and Architecture; Section III. on Physics, Chemistry, and Biology will find a chairman in Dr. Sims Woodhead. The popular lecture is to be delivered by Dr. Alex. Hill, Master of Downing College and Vice-chancellor of Cambridge University. Various excursions to places of interest in the locality have been arranged, as also visits to the leading firms of manufacturers in the town and district. Altogether the meeting is looked forward to with considerable interest and the local committee are to be congratulated upon the extensive and elaborate arrangements made for the reception and edification of the visitors.

THE TYPHOID FEVER EPIDEMIC AT BELFAST.—It is to be hoped that Belfast is over the worst of the typhoid fever epidemic, as the number of cases notified is becoming distinctly less. 41 were reported on Saturday and on Sunday and Monday the aggregate was 71. There are between 300 and 400 cases in the Union Fever Hospital. The authorities there have decided upon using exclusively for typhoid fever patients a large additional building, formerly a convalescent hospital occupied by old and infirm men. These aged paupers have been removed to other parts of the house and this extensive edifice will accommodate 300 typhoid fever patients. It is 151 ft. long, 42 ft. broad, and has three storeys and a very serviceable lift. Two additional resident medical men have been appointed as well as twelve extra nurses. The guardians are also providing another ambulance to convey patients into hospital. The public health offices are constantly open and the officials are most active. Disinfectants are there supplied to the public and the printed instructions of the medical officer of health as to how the citizens should act in reference to the present outbreak are being distributed broadcast. The medical officer of health (Dr. Whitaker) and Dr. Lorrain Smith (Pathologist to the Corporation) are investigating the causes of the epidemic, and at present a bacteriological examination is being made of the water supplied to the city. At the next meeting of the corporation it is expected that there will be a discussion in reference to the epidemic. It is a satisfactory circumstance that although there is a widespread epidemic of typhoid fever the mortality is not high.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students, we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies will be found.*

TO ADVERTISERS.

Owing to the pressure on our advertisement columns this week many announcements have unavoidably been held over.

Communications, Letters, &c., have been received from—

A.—Mr. W. D. Akers, Bath; Mons. J. Astier, Paris; A. J.

B.—Mons. O. Berthier, Paris; Mr. C. J. Bond, Leicester; Messrs. Boot and Son, Lond.; Dr. L. S. Beale, Lond.; T. B. Browne, Ltd., Lond.; Bankruptcy Court, Official Receiver of; Dr. E. C. Baber, Brighton; Messrs. Bates, Hendy, and Co., Lond.; Mr. L. Browne, Lond.; Bethnal Green Free Library, Lond.; Mr. F. Burton, St. Leonards; Mr. M. L. Bensusan, Lond.; Mr. A. E. Barker, Parkstone.

C.—Mr. H. W. Cox, Lond.; Dr. C.; C. S.; Messrs. T. Christy and Co., Lond.; Mr. J. Collinson, Lond.; Cortland Wagon Co., Lond.; Mr. Coxon, Wisbech; Mr. W. E. Cooper, Lond.; Cornwall County Asylum, Bodmin, Secretary of.

E.—Dr. W. Edmunds, Lond.; Examination Hall, Lond., Secretary of; Exeter City Asylum, Medical Superintendent of.

F.—Mr. A. W. Forsaith, Lond.; Mr. Ferguson, Edinburgh; Mr. P. R. Fort, Lond.; Mr. A. G. R. Foulerton, Sutton.

G.—Mr. C. T. Gardner, Worthing; Glasgow Royal Infirmary, Superintendent of; Herr L. W. Gans, Frankfurt.

H.—Dr. T. W. Hime, Bradford; Mr. J. T. Hislop, Hampsthwaite.

I.—Isle of Thanet Union, Minster, Clerk of; *Il Policlinico*, Rome, Secretary of.

J.—Mr. W. H. Jalland, York; Dr. A. H. Jeremy, Ashford, Devon; J. B. C.; Jenner Institute for Calf Lymph, Lond.; J. S.; Mr. A. Jolly, Sunderland.

K.—Kronthal Co., Lond., Secretary of.

L.—Mr. C. Legg, Eastry; Dr. J. F. Little, Lond.; Messrs. T. Lewin and Co., Lond.; Lord, Aspinwall, and Co., Manchester; *La Médecine Infantile*, Paris; Messrs. E. and S. Livingstone, Edinburgh.

M.—Mr. W. J. Mulcahy, Lond.; Messrs. J. Maclehose and Sons, Glasgow; Mr. J. Murray, Lond.; Medical Society of Victoria, Melbourne, Hon. Secretary of; Dr. S. McDonald, Cumberland; Lady Mordaunt, Warwick.

N.—Nurses' Coöperation, Lond., Secretary of.

P.—Mr. F. Pope, Birmingham; Mr. Y. J. Pentland, Edinburgh; Messrs. Potter and Sacker, Lond.

R.—Dr. W. R. Rice, Coventry; Mr. C. E. Richmond, Manchester; Reliance Pen Co., Manchester; Royal Southern Hospital, Liverpool, Secretary of; Dr. C. Reinhardt, Reading; Messrs. Reynolds and Branson, Leeds.

S.—Mr. A. Stenhouse, Glasgow; Messrs. J. P. Segg and Co., Lond.; Surgical Supply Association, Manchester; Mr. F. O. Stocker, Lond.; St. Mungo's College, Glasgow; Messrs. Street and Co., Lond.; Dr. Spence, Burntwood.

T.—Dr. T. R. Taylor, Lond.; Messrs. J. Turner and Co., Queen's Ferry; Dr. C. H. Thompson, Lond.

U.—University of the State of New York, Secretary of.

V.—Vinolia Co., Lond.

W.—Mr. C. Hamilton Whiteford, Plymouth; Messrs. Woolley, Sons, and Co., Manchester; Mr. S. Wand, Leicester; Mr. Walker, Aberdeen; Dr. Welsh, Whitworth; Mr. C. H. Wells, Lond.; Dr. A. S. Wilson, St. Leonards-on-Sea; Western General Dispensary, Hon. Secretary of; Mr. W. R. Williams, Clifton.

X.—X.

Letters, each with enclosure, are also acknowledged from—

B.—Mr. T. Bell, Lancaster; Mr. J. C. Bowie, Clousta, Shetland; Birmingham City Asylum, Clerk of; Messrs. Burgoyne, Burbidges, and Co., Lond.; Messrs. A. and C. Black, Lond.; Messrs. W. and G. Baird, Belfast; Mr. C. Birchall, Liverpool; B. P.; Mrs. S. A. Bennett, Lond.; Mr. C. L. Bedford, Birmingham; Mr. T. W. Brimacombe, Kingswood Park.

C.—Mr. H. C. Coopland, Sunderland; Messrs. Clarke, Son, and Platt, Lond., Messrs. Cuff Bros., Dover; Coachman, Bangor; Mr. H. Cuthbert, Ashton-on-Clun; Messrs. Caldwell, Muir, and Caldwell, Paisley; C. B. M.; C. G. S.; Mr. W. J. Crick, Bexhill-on-Sea; C. E. P.; Capel Lodge, Folkestone, Proprietor of.

D.—Dr. W. D. Donnan, Holywood; Mr. A. K. Dresser, Padstow; Dr. W. C. Dale, Lond.; D. A. B.; Mr. L. B. Dhargalker, Bombay; Messrs. A. De St. Dalmas and Co., Leicester.

E.—Mr. H. S. Elworthy, Lond.; Mr. F. Edwards, Sawston; E. B.; E. W. S.

F.—Mr. J. FitzGerald, Queenstown; Mr. R. Friel, Hereford; F. E. S.; F. F. P.; F. W. T.; F.W.

G.—General Medical Council, Registrar of.

H.—Mr. W. C. Herring, Vert, France; Dr. W. K. Hunter, Glasgow; Mr. J. Hart, Lond.; Haydock Lodge, Newton-le-Willows; H. J. W.; Mr. H. R. Hancock, Paignton; H. B. W.

J.—Mr. C. S. Jago, St. Just; J. M. B.; J. W. G.; J. G. B.; J. P.; J. B. S.; Dr. W. B. Jones, Llangammarch.

Presidential Address

ON

THE WHEAT-SUPPLY OF THE WORLD, THE LATEST ACHIEVEMENTS OF SCIENCE, AND THE POSITION OF PSYCHICAL RESEARCH.

Delivered before the British Association for the Advancement of Science at Bristol on Wednesday, September 7th,

BY SIR WILLIAM CROOKES, F.R.S.,

PRESIDENT OF THE ASSOCIATION; PRESIDENT OF THE SOCIETY FOR PSYCHICAL RESEARCH; AND VICE-PRESIDENT OF THE CHEMICAL SOCIETY.

GENTLEMEN,—For the third time in its history the British Association meets in your city of Bristol. The first meeting was held under the presidency of the Marquis o Lansdowne in 1836, the second under the presidency of Sir John Hawkshaw in 1875. Formerly the President unrolled to the meeting a panorama of the year's progress in physical and biological sciences. To-day the President usually restricts himself to specialities connected with his own work or deals with questions which for the time are uppermost. To be President of the British Association is undoubtedly a great honour. It is also a great opportunity and a great responsibility, for I know that, on the wings of the Press, my words, be they worthy or not, will be carried to all points of the compass. I propose first to deal with the important question of the supply of bread to the inhabitants of these islands, then to touch on subjects to which my life work has been more or less devoted. I shall not attempt any general survey of the sciences; these, so far as the progress in them demands attention, will be more fitly brought before you in the different sections either in the Addresses of the Presidents or in communications from members. Before proceeding with my address I wish to refer to the severe loss the British Association has sustained in the death of Lord Playfair. With Sir John Lubbock and Lord Rayleigh, Lord Playfair was one of the permanent trustees of our Association and for many years he was present at our meetings. It would be difficult to over-rate his loss to British science. Lord Playfair's well-matured and accurate judgment, his scientific knowledge, and his happy gift of clothing weighty thoughts in persuasive language made his presence acceptable, whether in the council chamber, in departmental inquiries, or at light social gatherings, where by the singular laws of modern society momentous announcements are sometimes first given to the world. Lord Playfair (then Sir Lyon Playfair) was President of the British Association at Aberdeen in 1885; his address on that occasion will long be remembered as a model of profound learning and luminous exposition.

And now I owe a sort of apology to this brilliant audience. I must ask you to bear with me for ten minutes, for I am afraid what I now have to say will prove somewhat dull. I ought to propitiate you, for, to tell the truth, I am bound to bore you with figures. Statistics are rarely attractive to a listening audience, but they are necessary evils, and those of this evening are unusually doleful. Nevertheless, when we have proceeded a little way on our journey I hope you will see that the river of figures is not hopelessly dreary. The stream leads into an almost unexplored region and to the right and left we see channels opening out, all worthy of exploration and promising rich reward to the statistic explorer who will trace them to their source—a harvest, as Huxley expresses it, "immediately convertible into those things which the most sordidly practical of men will admit to have value—namely, money and life." My chief subject is of interest to the whole world, to every race, to every human being. It is of urgent importance to-day and it is a life and death question for generations to come—I mean the question of food-supply.

I.—THE WHEAT-SUPPLY OF THE WORLD.

Many of my statements you may think are of the alarmist order; certainly they are depressing, but they are founded on stubborn facts. They show that England and all civilised nations stand in deadly peril of not having enough to eat. As mouths multiply food resources dwindle. Land is a limited quantity and the land that will grow wheat is absolutely dependent on difficult and capricious natural phenomena. I am constrained to show that our wheat-producing soil is totally unequal to the strain put upon it. After wearying you with a survey of the universal dearth to be expected I hope to point a way out of the colossal dilemma. It is the chemist who must come to the rescue of the threatened communities. It is through the laboratory that starvation may ultimately be turned into plenty.

The Food-supply of Great Britain.

The food-supply of the kingdom is of peculiar interest to this meeting, considering that the grain trade has always been, and still is, an important feature in the imports of Bristol. The imports of grain to this city amount to about 25,000,000 bushels per annum, 8,000,000 of which consist of wheat. What are our home requirements in the way of wheat? The consumption of wheat per head of the population (unit consumption) is over 6 bushels per annum; and taking the population at 40,000,000 we require no less than 240,000,000 bushels of wheat, increasing annually by 2,000,000 bushels, to supply the increase of population. Of the total amount of wheat consumed in the United Kingdom we grow 25 and import 75 per cent. So important is the question of wheat-supply that it has attracted the attention of Parliament and the question of national granaries has been mooted. It is certain that in case of war with any of the great powers wheat would be contraband, as if it were cannon or powder liable to capture even under a neutral flag. We must therefore accept the situation and treat wheat as munitions of war, and grow, accumulate, or store it as such. It has been shown that at the best our stock of wheat and flour amounts only to 64,000,000 bushels—fourteen weeks' supply—while last April our stock was equal to only 10,000,000 bushels, the smallest ever recorded by "Beerbohm" for the period of the season. Similarly, the stocks held in Europe, the United States, and Canada, called "the world's visible supply," amounted to only 54,000,000 bushels, or 10,000,000 less than last year's sum total, and nearly 82,000,000 less than that of 1893 or 1894 at the corresponding period. To arrest this impending danger it has been proposed that an amount of 64,000,000 bushels of wheat should be purchased by the State and stored in national granaries, not to be opened except to remedy deterioration of grain or in view of national disaster rendering starvation imminent. This 64,000,000 bushels would add another fourteen weeks' life to the population; assuming that the ordinary stock had not been drawn on, the wheat in the country would only then be enough to feed the population for twenty-eight weeks. I do not venture to speak authoritatively on national granaries. The subject has been discussed in the daily press and the recently published report from the Agricultural Committee on National Wheat Stores brings together all the arguments in favour of this important scheme, together with the difficulties to be faced if it be carried out with necessary completeness.

More hopeful, although difficult and costly, would be the alternative of growing most, if not all, of our own wheat-supply here at home in the British Isles. The average yield over the United Kingdom last year was 29·07 bushels per acre, the average for the last eleven years being 29·46. For twelve months we need 240,000,000 bushels of wheat, requiring about 8,250,000 acres of good wheat-growing land, or nearly 13,000 square miles, increasing at the rate of 100 square miles per annum, to render us self-supporting as to bread food. This area is about one-fourth of the size of England.[1] A total area of land in the United Kingdom equal to a plot 110 miles square, of quality and climate sufficient to grow wheat to the extent of 29 bushels per acre, does not seem a hopeless demand.[2] It is doubtful, however, if this amount of land could be kept under wheat and the necessary expense of high farming faced except under the imperious pressure of impending starvation or the stimulus of a national subsidy or permanent high prices. Certainly these 13,000 square miles would not be

[1] In preparing the part of this address dealing with the world's supply and demand for wheat and the conclusions thereon I have been materially assisted by Mr. C. Wood Davis of Kansas, U.S.A.

[2] The total area of the United Kingdom is 120,979 square miles; therefore the required land is about a tenth part of the total.

Digitized by Google

available under ordinary economic conditions, for much, perhaps all, the land now under barley and oats would not be suitable for wheat. In any case, owing to our cold, damp climate and capricious weather, the wheat crop is hazardous and for the present our annual deficit of 180,000,000 bushels must be imported. A permanently higher price for wheat is, I fear, a calamity that ere long must be faced. At enhanced prices land now under wheat will be better farmed and therefore will yield better, thus giving increased production without increased area. The burning question of to-day is, What can the United Kingdom do to be reasonably safe from starvation in presence of two successive failures of the world's wheat harvest or against a hostile combination of European nations? We eagerly spend millions to protect our coasts and commerce, and millions more on ships, explosives, guns, and men, but we omit to take necessary precautions to supply ourselves with the very first and supremely important munition of war—food.

The Bread-Eaters of the World.

To take up the question of food-supply in its scientific aspect I must not confine myself exclusively to our own national requirements. The problem is not restricted to the British Isles—the bread-eaters of the whole world share the perilous prospect—and I do not think it out of place if on this occasion I ask you to take with me a wide, general survey of the wheat-supply of the whole world. Wheat is the most sustaining food grain of the great Caucasian race which includes the peoples of Europe, United States, British America, the white inhabitants of South Africa, Australasia, parts of South America, and the white population of the European colonies. Of late years the individual consumption of wheat has almost universally increased. In Scandinavia it has risen 100 per cent. in 25 years; in Austro-Hungary, 80 per cent.; in France, 20 per cent.; while in Belgium it has increased 50 per cent. Only in Russia and Italy, and possibly Turkey, has the consumption of wheat per head declined. In 1871 the bread-eaters of the world numbered 371,000,000, In 1881 the numbers rose to 416,000,000; in 1891, to 472,600,000; and at the present time they number 516,500,000. The augmentation of the world's bread-eating population in a geometrical ratio is evidenced by the fact that the yearly aggregates grow progressively larger. In the early seventies they rose 4,300,000 per annum, while in the eighties they increased by more than 6,000,000 per annum, necessitating annual additions to the bread-supply nearly one-half greater than sufficed twenty-five years ago. How much wheat will be required to supply all these hungry mouths with bread? At the present moment it is not possible to get accurate estimates of this year's wheat crops of the world, but an adequate idea may be gained from the realised crops of some countries and the promise of others. To supply 516,500,000 bread-eaters, if each bread-eating unit is to have his usual ration, will require a total of 2,324,000,000 bushels for seed and food. What are our prospects of obtaining this amount?

According to the best authorities the total supplies from the 1897–98 harvest are 1,921,000,000 bushels. The requirement of the 516,500,000 bread-eaters for seed and food are 2,324,000,000 bushels; there is thus a deficit of 403,000,000 bushels, which has not been urgently apparent owing to a surplus of 300,000,000 bushels carried over from the last harvest. Respecting the prospects of the harvest year just beginning it must be borne in mind that there are no remainders to bring over from the last harvest. We start with a deficit of 103,000,000 bushels and have 6,500,000 more mouths to feed. It follows, therefore, that one-sixth of the required bread will be lacking unless larger drafts than now seem possible can be made upon early produce from the next harvest. The majority of the wheat crops between 1882 and 1896 were in excess of current needs, and thus considerable reserves of wheat were available for supplementing small deficits from the four deficient harvests. But bread-eaters have almost eaten up the reserves of wheat, and the 1897 harvest being under average the conditions become serious. That scarcity and high prices have not prevailed in recent years is due to the fact that since 1889 we have had seven world crops of wheat and six of rye abundantly in excess of the average. These generous crops increased accumulations to such an extent as to obscure the fact that the harvests of 1895 and 1896 were each much below current requirements. Practically speaking, reserves are how exhausted and bread-eaters must be fed from current harvests—accumulation under present conditions being almost impossible. This is obvious from the fact that a harvest equal to that of 1894 (the greatest crop on record both in acre-yield and in the aggregate) would yield less than current needs. It is clear we are confronted with a colossal problem that must tax the wits of the wisest. When the bread-eaters have exhausted all possible supplies from the 1897–98 harvest there will be a deficit of 103,000,000 bushels of wheat, with no substitution possible unless Europeans can be induuced to eat Indian corn or rye-bread. Up to recent years the growth of wheat has kept pace with demands. As wheat-eaters increased the acreage under wheat expanded. The world has become so familiarised with the orderly sequence of demand and supply, so accustomed to look upon the vast plains of other wheat-growing countries as inexhaustible granaries, that, in a light-hearted way, it is taken for granted that so many million additional acres can be added year after year to the wheat-growing area of the world. We forget that the wheat-growing area is of strictly limited extent and that a few million acres regularly absorbed soon mount to a formidable number.

The Capabilities of the Wheat-growing Countries: the United States.

The present position being so gloomy, let us consider future prospects. What are the capabilities as regards available area, economic conditions, and acreage yield of the wheat-growing countries whence we now draw our supply? For the last thirty years the United States have been the dominant factor in the foreign supply of wheat, exporting no less than 145,000,000 bushels. This shows how the bread-eating world has depended, and still depends, on the United States for the means of subsistence. The entire world's contributions to the food-bearing area have averaged but 4,000,000 acres yearly since 1869. It is scarcely possible that such an average under existing conditions can be doubled for the coming twenty-five years. Almost yearly since 1885 additions to the wheat-growing area have diminished, while the requirements of the increasing population of the States have advanced, so that the needed American supplies have been drawn from the acreage hitherto used for exportation. Practically there remains no uncultivated prairie land in the United States suitable for wheat-growing. The virgin land has been rapidly absorbed until at present there is no land left for wheat without reducing the area for maize, hay, and other necessary crops. It is almost certain that within a generation the ever-increasing population of the United States will consume all the wheat grown within its borders and will be driven to import, and, like ourselves, will scramble for a lion's share of the wheat crop of the world. This being the outlook exports of wheat from the United States are only of present interest and will gradually diminish to a vanishing point. The inquiry may be restricted to such countries as probably will continue to feed bread-eaters who annually derive a considerable part of their wheat from extraneous sources. But if the United States, which grow about one-fifth of the world's wheat and contribute one-third of all wheat exportations, are even now dropping out of the race and likely soon to enter the list of wheat-importing countries, what prospect is there that other wheat-growing countries will be able to fill the gap and by enlarging their acreage under wheat replace the supply which the States have so long contributed to the world's food? The withdrawal of 145,000,000 bushels will cause a serious gap in the food-supply of wheat-importing countries and unless this deficit can be met by increased supplies from other countries there will be a dearth for the rest of the world after the British Isles are sufficiently supplied.

Russia.

Next to the United States Russia is the greatest wheat exporter, supplying nearly 95,000,000 bushels. Although Russia at present exports so lavishly this excess is merely provisional and precarious. The Russian peasant population increases more rapidly than any other in Europe. The yield per acre over European Russia is meagre—not more than 8·6 bushels to the acre—while some authorities consider it as low as 4·6 bushels. The cost of production is low—lower even than on the virgin soil of the United States. The development of the fertile though somewhat overrated "black earth," which extends across the southern portion of the empire and beyond the Ural Mountains into Siberia, progresses rapidly. But, as we have indicated, the consumption of bread in Russia has been reduced to danger point. The peasants starve and fall victims to "hunger

Digitized by Google

typhus," whilst the wheat-growers export grain that ought to be consumed at home. Considering Siberia as a wheat-grower, climate is the first consideration. Summers are short—as they are in all regions with continental climates north of the 45th parallel—and the ripening of wheat requires a temperature averaging at least 65° F. for from 55 to 65 days. As all Siberia lies north of the summer isotherm of 65° it follows that such region is ill-adapted to wheat culture unless some compensating climatic condition exists. As a fact, the conditions are exceptionally unfavourable in all but very limited districts in the two westernmost governments. The cultivable lands of Western Siberia adapted to grain-bearing neither equal in extent nor in potential productive powers those of Iowa, Minnesota, and Nebraska. There are limited tracts of fair productiveness in Central Siberia and in the valleys of the southern affluents of the Amoor, but these are only just capable of supporting a meagre population. Prince Hilkoff, Russian Minister of Ways and Communications, declared in 1896 that "Siberia never had produced, and never would produce, wheat and rye enough to feed the Siberian population." And a year later Prince Krapotkin backed the statement as substantially correct.

Canada.

Those who attended the meeting of the British Association last year in Canada must have been struck with the extent and marvellous capacity of the fertile plains of Manitoba and the North-West provinces. Here were to be seen 1,290,000 acres of fine wheat-growing land yielding 18,261,950 bushels, one-fifth of which comes to hungry England. Expectations have been cherished that the Canadian North-West would easily supply the world with wheat, and exaggerated estimates are drawn as to the amount of surplus land on which wheat can be grown. Thus far performance has lagged behind promise, the wheat-bearing area of all Canada having increased less than 500,000 acres since 1884, while the exports have not increased in greater proportion. As the wheat area of Manitoba and the North-West has increased the wheat area of Ontario and the Eastern provinces has decreased, the added acres being little more than sufficient to meet the growing requirements of population. We have seen calculations showing that Canada contains 500,000,000 acres of profitable wheat land. The impossibility of such an estimate ever being fulfilled will be apparent when it is remembered that the whole area employed in both temperate zones for growing all the staple food crops is not more than 580,000,000 acres, and that in no country has more than 9 per cent. of the area been devoted to wheat culture. The fertility of the North-West provinces of the Dominion is due to an exceptional and curious circumstance. In winter the ground freezes to a considerable depth. Wheat is sown in the spring, generally April, when the frozen ground has been thawed to a depth of 3 in. Under the hot sun of the short summer the grain sprouts with surprising rapidity, partly because the roots are supplied with water from the thawing depths. The summer is too short to thaw the ground thoroughly and gate-posts or other dead wood extracted in autumn are found still frozen at their lower ends.

Australasia.

Australasia as a potential contributor to the world's supply of wheat affords another fertile field for speculation. Climatic conditions limit the Australian wheat area to a small portion of the southern littoral belt. Professor Shelton considers there are still 50,000,000 acres in Queensland suitable for wheat, but hitherto it has never had more than 150,000 acres under cultivation. Crops in former days were liable to rust, but since the conferences on rust in wheat and the dissemination of instruction to farmers rust no longer has any terrors. I am informed by the Queensland Department of Agriculture that of late years they practically have bred wheat vigorous enough to resist this plague. For the second season in succession the wheat crop last year was destroyed over large areas in Victoria; and in South Australia the harvest averaged not more than about 3¾ bushels per acre after meeting colonial requirements for food and seed, leaving only 684,000 bushels for export. In most other districts the yield falls to such an extent as to cause Europeans to wonder why the pursuit of wheat-raising is continued.

New Zealand has a moist climate resembling that of central and southern England, while South Australia is semi-arid, resembling western Kansas. Only two countries in the world yield as much wheat per acre as New Zealand—these are Denmark and the United Kingdom. Notwithstanding the great yield of wheat, due to an equable climate, New Zealand finds fruit and dairy farming still more profitable. The climatic conditions favourable to wheat are also conducive to luxuriant growths of nutritious grasses. Thus the New Zealander ships his butter more than half way round the world and competes successfully with western Europe.

Austro-Hungary and other European States.

During the last twenty-seven years the Austro-Hungarian population has increased 21·8 per cent., as against an increase of 54·6 per cent. in the acreage of wheat. Notwithstanding this disparity in the rates of increase exports have practically ceased by reason of an advance of nearly 80 per cent. in unit consumption. There can be little doubt that Austro-Hungary is about to enter the ranks of importing nations, although in Hungary a considerable area of wheat land remains to be brought under cultivation.

Roumania is an important wheat-growing country. In 1896 it produced 69,000,000 bushels and exported 34,000,000 bushels. It has a considerable amount of surplus land which can be used for wheat, although for many years the wheat area is not likely to exceed home requirements. France comes next to the United States as a producer of wheat; but for our purpose she counts but little, being dependent on supplies from abroad for an average quantity of 14 per cent. of her own production. There is practically no spare land in France that can be put under wheat in sufficient quantity to enable her to do more than provide for increase of population. Germany is a gigantic importer of wheat, her imports rising 700 per cent. in the last twenty-five years, and now averaging 35,000,000 bushels. Other nations of Europe, also importers, do not require detailed mention, as under no conceivable conditions would they be able to do more than supply wheat for the increasing requirements of the local population, and instead of replenishing would probably diminish the world's stores.

Argentina and Uruguay.

The prospective supply of wheat from Argentina and Uruguay has been greatly overrated. The agricultural area includes less than 100,000,000 acres of good, bad, and indifferent land, much of which is best adapted for pastoral purposes. There is no prospect of Argentina ever being able to devote more than 30,000,000 acres to wheat; the present wheat area is about 6,000,000 acres, an area that may be doubled in the next twelve years. But the whole arable region is subject to great climatic vicissitudes and to frosts that ravage the fields south of the 37th parallel. Years of systematised energy are frustrated in a few days—perhaps hours—by a single cruelty of Nature, such as a plague of locusts, a tropical rain, or a devastating hail storm. It will take years to bring the surplus land of Argentina into cultivation and the population is even now insufficient to supply labour at seed time and harvest. During the next twelve years Uruguay may add 1,000,000 acres to the world's wheat fields; but social, political, and economic conditions seriously interfere with agricultural development.

Africa.

At the present time South Africa is an importer of wheat and the regions suitable to cereals do not exceed a few million acres. Great expectations have been formed as to the fertility of Mashonaland, the Shire Highlands, and the Kikuyu plateau, and as to the adaptation of these regions to the growth of wheat. But wheat culture fails where the banana ripens and the banana flourishes throughout Central Africa except in limited areas of great elevation. In many parts of Africa insect pests render it impossible to store grain and without grain-stores there can be little hope of large exports. North Africa, formerly the granary of Rome now exports less than 5,000,000 bushels of wheat annually, and these exports are on the decline owing to increased home demands. With scientific irrigation Egypt could supply three times her present amount of wheat, although no increase is likely unless the cotton fields of the Delta are diverted to grain-growing. In Algeria and Tunis nearly all reclaimed lands are devoted to the production of wine, for which a brisk demand exists. Were this land devoted to the growth of wheat an additional 5,000,000 bushels might be obtained.

India.

The enormous acreage devoted to wheat in India has been declining for some years and in 1895 over 20,000,000 acres

Digitized by Google

yielded 185,000,000 bushels. Seven-eighths of this harvest is required for native consumption and only one-eighth on an average is available for export. The annual increase of population is more than 3,000,000, demanding an addition to the food-bearing lands of not less than 1,800,000 acres annually. In recent years the increase has been less than one-fourth of this amount.

In surveying the limitations and vicissitudes of wheat crops I have endeavoured to keep free from exaggeration and have avoided insistance on doubtful points. I have done my best to get trustworthy facts and figures, but from the nature of the case it is impossible to attain complete accuracy. Great caution is required in sifting the numerous varying current statements respecting the estimated areas and total produce of wheat throughout the world. The more closely official estimates are examined the more defective are they found, and comparatively few figures are sufficiently well established to bear the deductions often drawn. In doubtful cases I have applied to the highest authorities in each country and in the case of conflicting accounts have taken data the least favourable to sensational or panic-engendering statements. In a few instances of accurate statistics their value is impaired by age; but for 95 per cent. of my figures I quote good authorities, while for the remaining 5 per cent. I rely on the best commercial estimates derived from the appearance of the growing crops, the acreage under cultivation, and the yield last year. The maximum probable error would make no appreciable difference in my argument.

The Meaning of the Figures.

The facts and figures I have set before you are easily interpreted. Since 1871 unit consumption of wheat, including seed, has slowly increased in the United Kingdom to the present amount of 6 bushels per head per annum; while the rate of consumption for seed and food by the whole world of bread-eaters was 4·15 bushels per unit per annum for the eight years ending 1878, and at the present time is 4·5 bushels. Under present conditions of low acre yield wheat cannot long retain its dominant position among the food-stuffs of the civilised world. The details of the impending catastrophe no one can predict, but its general direction is obvious enough. Should all the wheat-growing countries add to their area to the utmost capacity, on the most careful calculation the yield would give us only an addition of some 100,000,000 acres, supplying at the average world-yield of 12·7 bushels to the acre, 1,270,000,000 bushels, just enough to supply the increase of population among bread-eaters till the year 1931. At the present time there exists a deficit in the wheat area of 31,000 square miles—a deficit masked by the fact that the ten world crops of wheat harvested in the ten years ending 1896 were more than 5 per cent. above the average of the previous twenty-six years. When provision shall have been made, if possible, to feed 230,000,000 units likely to be added to the bread-eating populations by 1931—by the complete occupancy of the arable areas of the temperate zone now partially occupied—where can be grown the additional 330,000,000 bushels of wheat required ten years later by a hungry world? What is to happen if the present rate of population be maintained and if arable areas of sufficient extent cannot be adapted and made contributory to the subsistence of so great a host? Are we to go hungry and to know the trial of scarcity? That is the poignant question. Thirty years is but a day in the life of a nation. Those present who may attend the meeting of the British Association thirty years hence will judge how far my forecasts are justified. If bread fails—not only us, but all the bread-eaters of the world—what are we to do? We are born wheat-eaters. Other races, vastly superior to us in numbers, but differing widely in material and intellectual progress, are eaters of Indian corn, rice, millet, and other grains; but none of these grains have the food value, the concentrated health-sustaining power of wheat, and it is on this account that the accumulated experience of civilised mankind has set wheat apart as the fit and proper food for the development of muscle and brains. It is said that when other wheat-exporting countries realise that the States can no longer keep pace with the demand these countries will extend their area of cultivation and struggle to keep up the supply *pari passu* with the falling-off in other quarters. But will this comfortable and cherished doctrine bear the test of examination? Cheap production of wheat depends on a variety of causes, varying greatly in different countries. Taking the cost of producing a given quantity of wheat in the United Kingdom at 100*s*., the cost for the same amount in the United States is 67*s*., in India 66*s*., and in Russia 54*s*. We require cheap labour, fertile soil, easy transportation to market, low taxation and rent, and no export or import duties. Labour will rise in price and fertility diminish as the requisite manurial constituents in the virgin soil become exhausted. Facility of transportation to market will be aided by railways, but these are slow and costly to construct, and it will not pay to carry wheat by rail beyond a certain distance. These considerations show that the price of wheat tends to increase. On the other hand, the artificial impediments of taxation and customs duties tend to diminish as demand increases and prices rise.

The Chemist to the Rescue.

I have said that starvation may be averted through the laboratory. Before we are in the grip of actual dearth the chemist will step in and postpone the day of famine to so distant a period that we and our sons and grandsons may legitimately live without undue solicitude for the future. It is now recognised that all crops require what is called a "dominant" manure. Some need nitrogens, some potash, others phosphates. Wheat pre-eminently demands nitrogen, fixed in the form of ammonia or nitric acid. All other necessary constituents exist in the soil; but nitrogen is mainly of atmospheric origin, and is rendered "fixed" by a slow and precarious process which requires a combination of rare meteorological and geographical conditions to enable it to advance at a sufficiently rapid rate to become of commercial importance. There are several sources of available nitrogen. The distillation of coal in the process of gas-making yields a certain amount of its nitrogen in the form of ammonia; and this product, as sulphate of ammonia, is a substance of considerable commercial value to gas companies. But the quantity produced is comparatively small; all Europe does not yield more than 400,000 annual tons, and in view of the unlimited nitrogen required to substantially increase the world's wheat crop this slight amount of coal ammonia is not of much significance. For a long time guano has been one of the most important sources of nitrogenous manures, but guano deposits are so near exhaustion that they may be dismissed from consideration.

Much has been said of late years and many hopes raised by the discovery of Hellriegel and Wilfarth that leguminous plants bear on their roots nodosities abounding in bacteria endowed with the property of fixing atmospheric nitrogen; and it is proposed that the necessary amount of nitrogen demanded by grain crops should be supplied to the soil by cropping it with clover and ploughing in the plant when its nitrogen assimilisation is complete. But it is questionable whether such a mode of procedure will lead to the lucrative stimulation of crops. It must be admitted that practice has long been ahead of science and for ages farmers have valued and cultivated leguminous crops. The four-course rotation is turnips, barley, clover, wheat—a sequence popular more than two thousand years ago. On the Continent, in certain localities, there has been some extension of microbe cultivation; at home we have not reached even the experimental stage. Our present knowledge leads to the conclusion that the much more frequent growth of clover on the same land, even with successful microbe-seeding and proper mineral supplies, would be attended with uncertainty and difficulties. The land soon becomes what is called "clover-sick" and turns barren.

There is still another and invaluable source of fixed nitrogen. I mean the treasure locked up in the sewage and drainage of our towns. Individually the amount so lost is trifling, but multiply the loss by the number of inhabitants and we have the startling fact that in the United Kingdom we are content to hurry down our drains and watercourses into the sea fixed nitrogen to the value of no less than £16,000,000 per annum. This unspeakable waste continues and no effective and universal method is yet contrived of converting sewage into corn. Of this barbaric waste of manurial constituents Liebig nearly half a century ago wrote in these prophetic words: "Nothing will more certainly consummate the ruin of England than a scarity of fertilisers—it means a scarcity of food. It is impossible that such a sinful violation of the divine laws of nature should for ever remain unpunished, and the time will probably come for England sooner than for any other country when, with all her wealth in gold, iron, and coal, she will be unable to buy one-thousandth part of the food which she has during

Digitized by Google

hundreds of years thrown recklessly away." The more widely this wasteful system is extended, recklessly returning to the sea what we have taken from the land, the more surely and quickly will the finite stocks of nitrogen locked up in the oils of the world become exhausted. Let us remember that the plant creates nothing; there is nothing in bread which is not absorbed from the soil, and unless the abstracted nitrogen is returned to the soil its fertility must ultimately be exhausted. When we apply to the land nitrate of soda, sulphate of ammonia, or guano, we are drawing on the earth's capital, and our drafts will not perpetually be honoured. Already we see that a virgin soil cropped for several years loses its productive powers and without artificial aid becomes infertile. Thus the strain to meet demands is increasingly great. Witness the yield of 40 bushels of wheat per acre under favourable conditions dwindling through exhaustion of soil to less than 7 bushels of poor grain, and the urgency of husbanding the limited store of fixed nitrogen becomes apparent. The store of nitrogen in the atmosphere is practically unlimited, but it is fixed and rendered assimilable by plants only by cosmic processes of extreme slowness. The nitrogen which with a light heart we liberate in a battleship broadside has taken millions of minute organisms patiently working for centuries to win from the atmosphere.[3]

Nitrogenous Manures.

The only available compound containing sufficient fixed nitrogen to be used on a world-wide scale as a nitrogenous manure is nitrate of soda, or Chili saltpetre. This substance occurs native over a narrow band of the plain of Tamarugal, in the northern provinces of Chili between the Andes and the coast hills. In this rainless district for countless ages the continuous fixation of atmospheric nitrogen by the soil, its conversion into nitrate by the slow transformation of billions of nitrifying organisms, its combination with soda and the crystallisation of the nitrate have been steadily proceeding, until the nitrate fields of Chili have become of vast commercial importance and promise to be of inestimably greater value in the future. The growing exports of nitrate from Chili at present amount to about 1,200,000 tons. The present acreage devoted to the world's growth of wheat is about 163,000,000 acres. At the average of 12·7 bushels per acre this gives 2,070,000,000 bushels. But thirty years hence the demands will be 3,260,000,000 bushels and there will be difficulty in finding the necessary acreage on which to grow the additional amount required. By increasing the present yield per acre from 12·7 to 20 bushels we should with our present acreage secure a crop of the requisite amount. Now from 12·7 to 20 bushels per acre is a moderate increase of productiveness, and there is no doubt that a dressing with nitrate of soda will give this increase and more. The action of nitrate of soda in improving the yield of wheat has been studied practically by Sir John Lawes and Sir Henry Gilbert on their experimental field at Rothamstead. This field was sown with wheat for thirteen consecutive years without manure and yielded an average of 11·9 bushels to the acre. For the next thirteen years it was sown with wheat and dressed with 5 cwt. of nitrate of soda per acre, other mineral constituents also being present. The average yield for these years was 36·4 bushels per acre—an increase of 24·5 bushels. In other words, 22·86 lb. of nitrate of soda produce an increase of one bushel of wheat. At this rate, to increase the world's crop of wheat by 7·3 bushels about 1¼ cwt. of nitrate of soda must annually be applied to each acre. The amount required to raise the world's crop on 163,000,000 acres from the present supply of 2,070,000,000 bushels to the required 3,260,000,000 bushels would be 12,000,000 tons distributed in varying amounts over the wheat-growing countries of the world. The countries which produce more than the average of 12·7 bushels will require less and those below the average will require more; but, broadly speaking, about 12,000,000 tons annually of nitrate of soda will be required, in addition to the 1,250,000 tons already absorbed by the world. It is difficult to get trustworthy estimates of the amount of nitrate surviving in the nitre beds. Common rumour declares the supply to be inexhaustible, but cautious local authorities state that at the present rate of export of over 1,000,000 tons per annum the raw material "caliche," containing from 25 to 50 per cent. nitrate, will be exhausted in from twenty to thirty years. Dr. Newton, who has spent years on the nitrate fields, tells me there is a lower class material, containing a small proportion of nitrate, which cannot at present be used, but which may ultimately be manufactured at a profit. Apart from a few of the more scientific manufacturers no one is sanguine enough to think this debatable material will ever be worth working. If we assume a liberal estimate for nitrate obtained from the lower grade deposit, and say that it will equal in quantity that from the richer quality, the supply may last, possibly, fifty years, at the rate of 1,000,000 tons a year; but at the rate required to augment the world's supply of wheat to the point demanded thirty years hence it will not last more than four years.

The Fixation of Nitrogen.

I have passed in review all the wheat-growing countries of the world, with the exception of those whose united supplies are so small as to make little appreciable difference to the argument. The situation may be summed up briefly thus: the world's demand for wheat—the leading bread-stuff—increases in a crescendo ratio year by year. Gradually all the wheat-bearing land on the globe is appropriated to wheat-growing until we are within measurable distance of using the last available acre. We must then rely on nitrogenous manures to increase the fertility of the land under wheat, so as to raise the yield from the world's low average—12·7 bushels per acre—to a higher average. To do this efficiently and feed the bread-eaters for a few years will exhaust all the available store of nitrate of soda. For years past we have been spending fixed nitrogen at a culpably extravagant rate, heedless of the fact that it is fixed with extreme slowness and difficulty, while its liberation in the free state takes place always with rapidity and sometimes with explosive violence. Some years ago Mr. Stanley Jevons uttered a note of warning as to the near exhaustion of our British coalfields. But the exhaustion of the world's stock of fixed nitrogen is a matter of far greater importance. It means not only a catastrophe little short of starvation for the wheat-eaters, but indirectly scarcity for those who exist on inferior grains, together with a lower standard of living for meat-eaters, scarcity of mutton and beef, and even the extinction of gunpowder!

There is a gleam of light amid this darkness of despondency. In its free state nitrogen is one of the most abundant and pervading bodies on the face of the earth. Every square yard of the earth's surface has nitrogen gas pressing down on it to the extent of about seven tons—but this is in the *free* state and wheat demands it *fixed*. To convey this idea in an object lesson I may tell you that, previously to its destruction by fire, Colston Hall, measuring 146 ft. by 80 ft. by 70 ft., contained 27 tons weight of nitrogen in its atmosphere; it also contained one-third of a ton of argon. In the free gaseous state this nitrogen is worthless; combined in the form of nitrate of soda it would be worth about £2000. For years past attempts have been made to effect the fixation of atmospheric nitrogen and some of the processes have met with sufficient partial success to warrant experimentalists in pushing their trials still further; but I think I am right in saying that no process has yet been brought to the notice of scientific or commercial men which can be considered successful either as regards cost or yield of product. It is possible, by several methods, to fix a certain amount of atmospheric nitrogen; but to the best of my knowledge no process has hitherto converted more than a small amount, and this at a cost largely in excess of the present market value of fixed nitrogen. The fixation of atmospheric nitrogen, therefore, is one of the great discoveries awaiting the ingenuity of chemists. It is certainly deeply important in its practical bearings on the future welfare and happiness of the civilised races of mankind. This unfulfilled problem, which so far has eluded the strenuous attempts of those who have tried to wrest the secret from nature, differs materially from other chemical discoveries which are in the air, so to speak, but are not yet matured. The fixation of nitrogen is vital to the progress of civilised humanity. Other discoveries minister to our increased intellectual comfort, luxury, or convenience; they serve to make life easier, to hasten the acquisition of wealth, or to save time, health, or worry. The fixation of

[3] Sir Andrew Noble informs me that a first-class battleship would carry about 63 tons of cordite and we may suppose that in a general action 40 tons of this would be expended. Now at Trafalgar Nelson had 27 line-of-battle ships and the allied forces 33. If we suppose a similar number of modern battleships and first-class cruisers to be engaged and each to expend 40 tons of cordite, the total volume of nitrogen set free would be 302,400 cubic metres, or about 380 tons, equivalent to 2300 tons of nitrate of soda.

Digitized by Google

nitrogen is a question of the not far distant future. Unless we can class it among certainties to come the great Caucasian race will cease to be foremost in the world and will be squeezed out of existence by races to whom wheaten bread is not the staff of life.

Let me see if it is not possible even now to solve the momentous problem. As far back as 1892 I exhibited at one of the *soirées* of the Royal Society an experiment on "The Flame of Burning Nitrogen." I showed that nitrogen is a combustible gas, and the reason why when once ignited the flame does not spread through the atmosphere and deluge the world in a sea of nitric acid is that its igniting point is higher than the temperature of its flame—not therefore hot enough to set fire to the adjacent mixture. But by passing a strong induction current between terminals the air takes fire and continues to burn with a powerful flame, producing nitrous and nitric acids. This inconsiderable experiment may not unlikely lead to the development of a mighty industry destined to solve the great food problem. With the object of burning out nitrogen from air so as to leave argon behind Lord Rayleigh fitted up apparatus for performing the operation on a larger scale, and succeeded in effecting the union of 29 4 grammes of mixed nitrogen and oxygen at an expenditure of one horse-power. Following these figures it would require one Board of Trade unit to form 74 grammes of nitrate of soda, and therefore 14,000 units to form one ton. To generate electricity in the ordinary way with steam-engines and dynamos, it is now possible with a steady load night and day, and engines working at maximum efficiency, to produce current at a cost of one-third of a penny per Board of Trade unit. At this rate one ton of nitrate of soda would cost £26. But electricity from coal and steam-engines is too costly for large industrial purposes; at Niagara, where water power is used, electricity can be sold at a profit for one-seventeenth of a penny per Board of Trade unit. At this rate nitrate of soda would cost not more than £5 per ton. But the limit of cost is not yet reached and it must be remembered that the initial data are derived from small scale experiments in which the object was not economy but rather to demonstrate the practicability of the combustion method and to utilise it for isolating argon. Even now electric nitrate at £5 a ton compares favourably with Chili nitrate at £7 10*s.* a ton; and all experience shows that when the road has been pointed out by a small laboratory experiment the industrial operations that may follow are always conducted at a cost considerably lower than could be anticipated from the laboratory figures.

Before we decide that electric nitrate is a commercial possibility a final question must be mooted. We are dealing with wholesale figures and must take care that we are not simply shifting difficulties a little further back without really diminishing them. We start with a shortage of wheat and the natural remedy is to put more land under cultivation. As the land cannot be stretched and there is so much of it and no more, the object is to render the available area more productive by a dressing with nitrate of soda. But nitrate of soda is limited in quantity and will soon be exhausted. Human ingenuity can contend even with these apparently hopeless difficulties. Nitrate can be produced artificially by the combustion of the atmosphere. Here we come to finality in one direction; our stores are inexhaustible. But how about electricity? Can we generate enough energy to produce 12,000,000 tons of nitrate of soda annually? A preliminary calculation shows that there need be no fear on that score; Niagara alone is capable of supplying the required electric energy without much lessening its mighty flow. The future can take care of itself. The artificial production of nitrate is clearly within view and by its aid the land devoted to wheat can be brought up to the 30 bushels per acre standard. In days to come, when the demand may again overtake supply, we may safely leave our successors to grapple with the stupendous food problem. And in the next generation, instead of trusting mainly to food-stuffs which flourish in temperate climates, we probably shall trust more and more to the exuberant food-stuffs of the tropics, where, instead of one yearly sober harvest, jeopardised by any shrinkage of the scanty days of summer weather or of the few steady inches of rainfall, Nature annually supplies heat and water enough to ripen two or three successive crops of food-stuffs in extraordinary abundance. To mention one plant alone, Humboldt—from what precise statistics I know not—computed that, acre for acre, the food-productiveness of the banana is 133 times that of wheat—the unripe banana, before its starch is converted into sugar, is said to make excellent bread. Considerations like these must in the end determine the range and avenues of commerce, perhaps the fate of continents. We must develop and guide Nature's latent energies, we must utilise her inmost workshops, we must call into commercial existence Central Africa and Brazil to redress the balance of Odessa and Chicago.

II.—THE LATEST ACHIEVEMENTS OF SCIENCE.

Having kept you for the last half-hour rigorously chained to earth disclosing dreary possibilities it will be a relief to soar to the heights of pure science and to discuss a point or two touching its latest achievements and aspirations. The low temperature researches which bring such renown to Professor Dewar and to his laboratory in the Royal Institution have been crowned during the present year by the conquest of one of Nature's most defiant strongholds. On May 10th last Professor Dewar wrote me these simple but victorious words: "This evening I have succeeded in liquefying both hydrogen and helium. The second stage of low temperature work has begun." Static hydrogen boils at a temperature of 238° C. at ordinary pressure and at 250° C. in a vacuum, thus enabling us to get within 23° C. of absolute zero. The density of liquid hydrogen is only one-fourteenth that of water, yet in spite of such a low density it collects well, drops easily, and has a well-defined meniscus. With proper isolation it will be as easy to manipulate liquid hydrogen as liquid air. The investigation of the properties of bodies brought near the absolute zero of temperature is certain to give results of extraordinary importance. Already platinum resistance thermometers are becoming useless, as the temperature of boiling hydrogen is but a few degrees from the point where the resistance of platinum would be practically nothing, or the conductivity infinite.

Several years ago I pondered on the constitution of matter in what I ventured to call the fourth state. I endeavoured to probe the tormenting mystery of the atom. What *is* the atom? Is a single atom in space solid, liquid, or gaseous? Each of these states involves ideas which can only pertain to vast collections of atoms. Whether, like Newton, we try to visualise an atom as a hard, spherical body or, with Boscovitch and Faraday, to regard it as a centre of force, or accept the vortex atom theory of Lord Kelvin, an isolated atom is an unknown entity difficult to conceive. The properties of matter—solid, liquid, gaseous—are due to molecules in a state of motion. Therefore, matter as we know it involves essentially a mode of motion and the atom itself — intangible, invisible, and inconceivable — is its material basis and may, indeed, be styled the only true *matter*. The space involved in the motions of atoms has no more pretension to be called matter than the sphere of influence of a body of riflemen — the sphere filled with flying leaden missiles—has to be called lead. Since what we call matter essentially involves a mode of motion, and since at the temperature of absolute zero all atomic motions would stop, it follows that matter as we know it would at that paralysing temperature probably entirely change its properties. Although a discussion of the ultimate absolute properties of matter is purely speculative it can hardly be barren, considering that in our laboratories we are now within moderate distance of the absolute zero of temperature. I have dwelt on the value and importance of nitrogen, but I must not omit to bring to your notice those little known and curiously related elements which during the past twelve months have been discovered and partly described by Professor Ramsay and Dr. Travers. For many years my own work has been among what I may call the waste heaps of the mineral elements. Professor Ramsay is dealing with vagrant atoms of an astral nature. During the course of the present year he has announced the existence of no fewer than three new gases—krypton, neon, and metargon. Whether these gases, chiefly known by their spectra, are true unalterable elements, or whether they are compounded of other known or unknown bodies, has yet to be proved. Fellow workers freely pay tribute to the painstaking zeal with which Professor Ramsay has conducted a difficult research, and to the philosophic subtlety brought to bear on his investigations. But, like most discoverers, he has not escaped the flail of severe criticism. There is still another claimant for celestial honours. Professor Nasini tells us he has discovered, in some volcanic gases at Pozzuoli, that hypothetical element coronium, supposed to cause the bright line 5316·9 in the spectrum of the sun's corona.

Digitized by Google

Analogy points to its being lighter and more diffusible than hydrogen and a study of its properties cannot fail to yield striking results. Still awaiting discovery by the fortunate spectroscopist are the unknown celestial elements, Aurorium—with a characteristic line at 5570·7—and Nebulum, having two bright lines at 5007·05 and 4959·02.

The fundamental discovery by Hertz of the electro-magnetic waves, predicted more than thirty years ago by Clerk Maxwell, seems likely to develop in the direction of a practical application which excites keen interest—I mean the application to electric signalling across moderate distances without connecting wires. The feasibility of this method of signalling has been demonstrated by several experimenters at more than one meeting of the British Association, though most elaborately and with many optical refinements by Oliver Lodge at the Oxford meeting in 1894. But not until Signor Marconi induced the British Post Office and foreign Governments to try large scale experiments did wireless signalling become generally and popularly known or practically developed as a special kind of telegraphy. Its feasibility depends on the discovery of a singularly sensitive detector for Hertz waves—a detector whose sensitiveness in some cases seems almost to compare with that of the eye itself. The fact noticed by Oliver Lodge in 1889 that an infinitesimal metallic gap subjected to an electric jerk became conducting, so as to complete an electric circuit, was rediscovered soon afterwards in a more tangible and definite form and applied to the detection of Hertz waves by M. E. Branly. Oliver Lodge then continued the work and produced the *vacuum filling-tube* coherers with automatic tapper-back, which are of acknowledged practical service. It is this varying continuity of contact under the influence of extremely feeble electric stimulus alternating with mechanical tremor, which, in combination with the mode of producing the waves revealed by Hertz, constitutes the essential and fundamental feature of "wireless telegraphy." There is a curious and widely spread misapprehension about coherers, to the effect that to make a coherer work the wave must fall upon it. Oliver Lodge has disproved this fallacy. Let the wave fall on a suitable receiver, such as a metallic wire, or, better still, on an arrangement of metal wings resembling a Hertz sender, and the waves set up oscillating currents which may be led by wires (enclosed in metal pipes) to the coherer. The coherer acts apparently by a species of end-impact of the oscillatory current and does not need to be attacked in the flank by the waves themselves. This interesting method of signalling—already developing in Marconi's hands into a successful practical system which inevitably will be largely used in lighthouse and marine work—presents more analogy to optical signals by flash-light than to what is usually understood as electric telegraphy; notwithstanding the fact that an ordinary Morse instrument at one end responds to the movements of a key at the other, or, as arranged by Alexander Muirhead, a syphon recorder responds to an automatic transmitter at about the rate of slow cable telegraphy. But although no apparent optical apparatus is employed, it remains true that the impulse travels from sender to receiver by essentially the same process as that which enables a flash of magnesium powder to excite a distant eye.

The phenomenon discovered by Zeeman that a source of radiation is affected by a strong magnetic field in such a way that light of one refrangibility becomes divided usually into three components, two of which are displaced by diffraction analysis on either side of the mean position and are oppositely polarised to the third or residual constituent, has been examined by many observers in all countries. The phenomenon has been subjected to photography with conspicuously successful results by Professor T. Preston in Dublin and by Professor Michelson and Dr. Ames and others in America. It appears that the different lines in the spectrum are differently affected, some of them being tripled with different grades of relative intensity, some doubled, some quadrupled, some sextupled, and some left unchanged. Even the two components of the D lines are not similarly influenced. Moreover, whereas the polarisation is usually such as to indicate that motions of a negative ion or electron constitute the source of light, a few lines are stated by the observers at Baltimore, who used what they call the "small" grating of 6 in. width ruled with 65,000 lines to be polarised in the reverse way. Further prosecution of these researches must lead to deeper insight into molecular processes and the mode in which they affect the ether; indeed, already valuable theoretic views have been promulgated by H. A. Lorenz, J. Larmer, and G. F. Fitzgerald, on the lines of the radiation theory of Dr. Johnstone Stoney; and the connexion of the new phenomena with the old magnetic rotation of Faraday is under discussion. It is interesting to note that Faraday and a number of more recent experimenters were led by theoretical considerations to look for some such effect; and though the inadequate means at their disposal did not lead to success, nevertheless a first dim glimpse of the phenomenon was obtained by M. Fieves of the Royal Observatory at Brussels in 1885.

The Roentgen Rays.

In the mechanical construction of Roentgen ray tubes I can record a few advances, the most successful being the adoption of Professor Silvanus P. Thompson's suggestion of using for the anti-cathode a metal of high atomic weight. Osmium and iridium have been used with advantage, and osmium anti-cathode tubes are now a regular article of manufacture. As long ago as June, 1896, x ray tubes with metallic uranium anti-cathodes were made in my own laboratory and were found to work better than those with platinum. The difficulty of procuring metallic uranium prevented these experiments from being continued. Thorium anti-cathodes have also been tried. Roentgen has drawn fresh attention to the fact very early observed by English experimenters—that of the non-homogeneity of the rays and the dependence of their penetrating power on the degree of vacuum; rays generated in high vacua have more penetrative power than when the vacuum is less high. These facts are familiar to all who have exhausted focus tubes on their own pumps. Roentgen suggests a convenient phraseology; he call a low vacuum tube, which does not emit the highly penetrating rays, a "soft" tube, and a tube in which the exhaustion has been pushed to an extreme degree, in which highly penetrating rays predominate, a "hard" tube. Using a "hard" tube he took a photograph of a double-barrelled rifle, and showed not only the leaden bullets within the steel barrels but even the wads and the charges. Benoit has re-examined the alleged relation between density and opacity to the rays and finds certain discrepancies. Thus the opacity of equal thicknesses of palladium and platinum are nearly equal, whilst their densities and atomic weights are very different, those of palladium being about half those of platinum. Meantime, while the general opinion of physicists seems to be settling towards a wave or ether theory for the Roentgen rays, an opposite drift is apparent with respect to the physical nature of the cathode rays; it becomes more and more clear that cathode rays consist of electrified atoms or ions in rapid progressive motion. My idea of a fourth state of matter, propounded in 1881,[4] and at first opposed at home and abroad, is now becoming accepted. It is supported by Professor J. J. Thomson[5]; Dr. Larmor's theory[6] likewise involves the idea of an ionic substratum of matter; the view is also confirmed by Zeeman's phenomenon. In Germany — where the term cathode ray was invented almost as a protest against the theory of molecular streams propounded by me at the Sheffield meeting of the British Association in 1879—additional proofs have been produced in favour of the doctrine that the essential fact in the phenomenon is electrified radiant matter. The speed of these molecular streams has been approximately measured chiefly by aid of my own discovery nearly twenty years ago that their path is curved in a magnetic field and that they produce phosphorescence where they impinge on an obstacle. The two unknown quantities, the charge and the speed of each atom, are measurable from the amount of curvature and by means of one other independent experiment. It cannot be said that a complete and conclusive theory of these rays has yet been formulated. It is generally accepted that collisions among particles, especially the violent collisions due to their impact on a massive target placed in their path, give rise to the interesting kind of extremely high frequency radiation discovered by Roentgen. It has, indeed, for some time been known that whereas a charged body in motion constitutes an electric current, the sudden stoppage or any violent acceleration of such a body must cause an alternative electric disturbance which, though so rapidly decaying in intensity as to be practically "dead beat," yet must give rise to an ethereal wave or pulse

travelling with the speed of light, but of a length comparable to the size of the body whose sudden change of motion caused the disturbance. The emission of a high-pitched musical sound from the jolting of a dustman's cart (with a spring bell hung on it) has been suggested as an illustration of the way in which the molecules of any solid not at absolute zero may possibly emit such rays. If the target on to which the electrically-charged atoms impinge is so constituted that some of its minute parts can thereby be set into rhythmical vibration, the energy thus absorbed reappears in the form of light, and the body is said to phosphoresce. The efficient action of the phosphorescent target appears to depend as much on its physical and molecular as on its chemical constitution. The best known phosphori belong to certain well-defined classes, such as the sulphides of the alkaline-earthy metals, and some of the so-called rare earths; but the phosphorescent properties of each of these groups are profoundly modified by an admixture of foreign bodies—witness the effect on the lines in the phosphorescent spectrum of yttrium and samarium produced by traces of calcium or lead. The persistence of the samarium spectrum in presence of overwhelming quantities of other metals is almost unexampled in spectroscopy; thus 1 part of samaria can easily be seen when mixed with 3,000,000 parts of lime. Without stating it as a general rule it seems as if with a non-phosphorescing target the energy of molecular impact reappears as pulses so abrupt and irregular that, when resolved, they furnish a copious supply of waves of excessively short wave-length—in fact, the now well-known Roentgen rays. The phosphorescence so excited may last only a small fraction of a second, as with the constituents of yttria, where the duration of the different lines varies between the 0·003 and the 0·0009 second; or it may linger for hours, as in the case of some of the yttria earths, and especially with the earthy sulphides, where the glow lasts bright enough to be commercially useful. Excessively phosphorescent bodies can be excited by light waves, but most of them require the stimulus of electrical excitement. It now appears that some bodies, even without special stimulation, are capable of giving out rays closely allied, if not in some cases identical, with those of Professor Roentgen. Uranium and thorium compounds are of this character and it would almost seem from the important researches of Dr. Russell that this ray-emitting power may be a general property of matter, for he has shown that nearly every substance is capable of affecting the photographic plate if exposed in darkness for sufficient time.

No other source for Roentgen rays but the Crookes's tube has yet been discovered, but rays of kindred sorts are recognised. The Becquerel rays, emitted by uranium and its compounds, have now found their companions in rays—discovered almost simultaneously by Curie and Schmidt—emitted by thorium and its compounds. The thorium rays affect photographic plates through screens of paper or aluminium and are absorbed by metals and other dense bodies. They ionise the air, making it an electrical conductor; and they can be refracted and probably reflected, at least diffusively. Unlike uranium rays, they are not polarised by transmission through tourmaline, therefore resembling in this respect the Roentgen rays. Quite recently M. and Madame Curie have announced a discovery which, if confirmed, cannot fail to assist the investigation of this obscure branch of physics. They have brought to notice a new constituent of the uranium mineral pitchblende, which in a 400-fold degree possesses uranium's mysterious power of emitting a form of energy capable of impressing a photographic plate and of discharging electricity by rendering air a conductor. It also appears that the radiant activity of the new body, to which the discoverers have given the name of polonium, needs neither the excitation of light nor the stimulus of electricity; like uranium, it draws its energy from some constantly regenerating and hitherto unsuspected store, exhaustless in amount. It has long been to me a haunting problem how to reconcile this apparently boundless outpour of energy with accepted canons. But, as Dr. Johnstone Stoney reminds me, the resources of molecular movements are far from exhausted. There are many stores of energy in nature that may be drawn on by properly constituted bodies without very obvious cause. Some time since I drew attention to the enormous amount of locked-up energy in the ether; nearer our experimental grasp are the motions of the atoms and molecules, and it is not difficult mentally so to modify Maxwell's demons as to reduce them to the level of an inflexible law and thus bring them within the ken of a philosopher in search of a new tool. It is possible to conceive a target capable of mechanically sifting from the molecules of the surrounding air the quick from the slow movers. This sifting of the swift-moving molecules is effected in liquids whenever they evaporate, and in the case of the constituents of the atmosphere wherever it contains constituents light enough to drift away molecule by molecule. In my mind's eye I see such a target as a piece of metal cooler than the surrounding air acquiring the energy that gradually raises its temperature from the outstanding effect of all its encounters with the molecules of the air about it; I see another target of such a structure that it throws off the slow-moving molecules with little exchange of energy, but is so influenced by the quick-moving missiles that it appropriates to itself some of their energy. Let uranium or polonium—bodies of densest atoms—have a structure that enables them to throw off the slow-moving molecules of the atmosphere, while the quick-moving molecules, smashing on to the surface, have their energy reduced and that of the target correspondingly increased. The energy thus gained seems to be employed partly in dissociating some of the molecules of the gas (or in inducing some other condition which has the effect of rendering the neighbouring air in some degree a conductor of electricity) and partly in originating an undulation through the ether, which, as it takes its rise in phenomena so disconnected as the impacts of the molecules of the air, must furnish a large contingent of light waves of short wave length. The shortness in the case of these Becquerel rays appears to approach without attaining the extreme shortness of ordinary Roentgen rays. The reduction of the speed of the quick moving molecules would cool the layer of air to which they belong; but this cooling would rapidly be compensated by radiation and conduction from the surrounding atmosphere; under ordinary circumstances the difference of temperature would scarcely be perceptible and the uranium would thus appear to perpetually emit rays of energy with no apparent means of restoration. The total energy of both the translational and internal motions of the molecules locked up in quiescent air at ordinray pressure and temperature is about 140,000 foot-pounds in each cubic yard of air. Accordingly the quiet air within a room 12 ft. high, 18 ft. wide, and 22 ft. long contains energy enough to propel a one-horse engine for more than twelve hours. The store drawn upon naturally by uranium and other heavy atoms only awaits the touch of the magic wand of Science to enable the twentieth century to cast into the shade the marvels of the nineteenth.

The Fractionation of Yttria.

Whilst placing before you the labours and achievements of my comrades in science I seize this chance of telling you of engrossing work of my own on the fractionation of yttria to which for the last eighteen years I have given ceaseless attention. In 1883, under the title of "Radiant Matter Spectroscopy," I described a new series of spectra produced by passing the phosphorescent glow of yttria, under molecular bombardment *in vacuo*, through a train of prisms. The visible spectra in time gave up their secrets and were duly embalmed in the Philosophical Transactions. At the Birmingham meeting of the British Association in 1886 I brought the subject before the Chemical Section, of which I had the honour to be President. The results led to many speculations on the probable origin of all the elementary bodies—speculations that for the moment I must waive in favour of experimental facts. There still remained for spectroscopic examination a long tempting stretch of unknown ultra-violet light, of which the exploration gave me no rest. But I will not now enter into details of the quest of unknown lines. Large quartz prisms, lenses, and condensers, specially sensitised photographic films capable of dealing with the necessary small amount of radiation given by feebly phosphorescing substances,[7] and, above all, tireless patience in collating and interpreting results, have all played their part. Although the research is incomplete I am able to announce that among the groups of rare earths giving phosphorescent spectra in the visible region there are others giving well-defined groups of bands which can only be recorded photographically. I have detected and mapped no less than six such groups extending to λ 3060.

[7] In this direction I am glad to acknowledge my indebtedness to Dr. Schuman, of Leipsic, for valuable suggestions and detail of his own apparatus, by means of which he has produced some unique records of metallic and gaseous spectra of lines of short wave-length.

Digitized by Google

Without enlarging on difficulties I will give a brief outline of the investigation. Starting with a large quantity of a group of the rare earths in a state of considerable purity a particular method of fractionation is applied, splitting the earths into a series of fractions differing but slightly from each other. Each of these fractions, phosphorescing *in vacuo*, is arranged in the spectrograph, and a record of its spectrum photographed upon a specially prepared sensitive film. In this way, with different groups of rare earths, the several invisible bands were recorded—some moderately strong, others exceedingly faint. Selecting a portion giving a definite set of bands, new methods of fractionation were applied, constantly photographing and measuring the spectrum of each fraction. Sometimes many weeks of hard experiment failed to produce any separation and then a new method of splitting up was devised and applied. By unremitting work—the solvent of most difficulties—eventually it was possible to split up the series of bands into various groups. Then, taking a group which seemed to offer possibilities of reasonably quick result, one method after another of chemical attack was adopted, with the ultimate result of freeing the group from its accompanying fellows and increasing its intensity and detail. As I have said, my researches are far from complete, but about one of the bodies I may speak definitely. High up in the ultra-violet, like a faint nebula in the distant heavens, a group of lines was detected, at first feeble and only remarkable on account of their isolation. On further purification these lines grew stronger. Their great refrangibility cut them off from other groups. Special processes were employed to isolate the earth, and using these lines as a test and appealing at every step to the spectrograph, it was pleasant to see how each week the group stood out stronger and stronger, while the other lines of yttrium, samarium, ytterbium, &c., became fainter, and at last practically vanishing left the sought-for group strong and solitary. Finally, within the last few weeks, hopefulness has emerged into certainty and I have absolute evidence that another member of the rare earth groups has been added to the list. Simultaneously with the chemical and spectrographic attack atomic weight determinations were constantly performed. As the group of lines which betrayed its existence stand alone, almost at the extreme end of the ultra-violet spectrum, I propose to name the newest of the elements Monium, from the Greek μόνος, alone. Although caught by the searching rays of the spectrum Monium offers a direct contrast to the recently discovered gaseous elements by having a strongly marked individuality; but although so young and wilful it is willing to enter into any number of chemical alliances. Until my material is in a greater state of purity I hesitate to commit myself to figures; but I may say that the wave-lengths of the principal lines are 3120 and 3117. Other fainter lines are at 3219, 3064, and 3060. The atomic weight of the element, based on the assumption of R_2O_3, is not far from 118—greater than that accepted for yttrium and less than that for lanthanum. I ought almost to apologise for adding to the already too long list of elements of the rare earth class—the asteriods of the terrestrial family. But as the host of celestial asteroids, unimportant individually, become of high interest when once the idea is grasped that they may be incompletely coagulated remains of the original nebula, so do these elusive and insignificant rare elements rise to supreme importance when we regard them in the light of component parts of a dominant element, frozen in embryo, and arrested in the act of coalescing from the original protyle into one of the ordinary and law-abiding family for whom Newlands and Mendeleeff have prepared pigeon-holes. The new element has another claim to notice. Not only is it new in itself, but to discover it a new tool had to be forged for spectroscopic research. Further details I will reserve for that tribunal before whom every aspirant for a place in the elemental hierarchy has to substantiate his claim.

III.—THE POSITION OF PSYCHICAL RESEARCH.

These, then, are some of the subjects, weighty and far-reaching, on which my own attention has been chiefly concentrated. Upon one other interest I have not yet touched—to me the weightiest and the farthest reaching of all. No incident in my scientific career is more widely known than the part I took many years ago in certain psychic researches. Thirty years have passed since I published an account of experiments tending to show that outside our scientific knowledge there exists a force exercised by intelligence differing from the ordinary intelligence common to mortals. This fact in my life is of course well understood by those who honoured me with the invitation to become your President. Perhaps among my audience some may feel curious as to whether I shall speak out or be silent. I elect to speak, although briefly. To enter at length on a still debatable subject would be unduly to insist on a topic which—as Wallace, Lodge, and Barrett have already shown — though not unfitted for discussion at these meetings, does not yet enlist the interest of the majority of my scientific brethren. To ignore the subject would be an act of cowardice—an act of cowardice I feel no temptation to commit. To stop short in any research that bids fair to widen the gates of knowledge, to recoil from fear of difficulty or adverse criticism, is to bring reproach on science. There is nothing for the investigator to do but to go straight on, "to explore up and down, inch by inch, with the taper his reason"; to follow the light wherever it may lead, even should it at times resemble a will-o'-the-wisp. I have nothing to retract. I adhere to my already published statements. Indeed, I might add much thereto. I regret only a certain crudity in those early expositions which, no doubt justly, militated against their acceptance by the scientific world. My own knowledge at that time scarcely extended beyond the fact that certain phenomena new to science had assuredly occurred, and were attested by my own sober senses, and, better still, by automatic record. I was like some two-dimensional being who might stand at the singular point of Riemann's surface, and thus find himself in infinitesimal and inexplicable contact with a plane of existence not his own. I think I see a little farther now. I have glimpses of something like coherence among the strange elusive phenomena—of something like continuity between those unexplained forces and laws already known. This advance is largely due to the labours of another association of which I have also this year the honour to be President—the Society for Psychical Research. And were I now introducing for the first time these inquiries to the world of science I should choose a starting-point different from that of old. It would be well to begin with *telepathy*; with the fundamental law, as I believe it to be, that thoughts and images may be transferred from one mind to another without the agency of the recognised organs of sense—that knowledge may enter the human mind without being communicated in any hitherto known or recognised ways.

Telepathy.

Although the inquiry has elicited important facts with reference to the mind it has not yet reached the scientific stage of certainty which would entitle it to be usefully brought before one of our sections. I will therefore confine myself to pointing out the direction in which scientific investigation can legitimately advance. If telepathy take place we have two physical facts—the physical change in the brain of A, the suggester, and the analogous physical change in the brain of B, the recipient of the suggestion. Between these two physical events there must exist a train of physical causes. Whenever the connecting sequence of intermediate causes begins to be revealed the inquiry will then come within the range of one of the sections of the British Association. Such a sequence can only occur through an intervening medium. All the phenomena of the universe are presumably in some way continuous, and it is unscientific to call in the aid of mysterious agencies when with every fresh advance in knowledge it is shown that ether vibrations have powers and attributes abundantly equal to any demand—even to the transmission of thought. It is supposed by some physiologists that the essential cells of nerves do not actually touch, but are separated by a narrow gap which widens in sleep while it narrows almost to extinction during mental activity. This condition is so singularly like that of a Branly or Lodge coherer as to suggest a further analogy. The structure of brain and nerve being similar it is conceivable there may be present masses of such nerve coherers in the brain whose special function it may be to receive impulses brought from without through the connecting sequence of ether waves of appropriate order of magnitude. Roentgen has familiarised us with an order of vibrations of extreme minuteness compared with the smallest waves with which we have hitherto been acquainted and of dimensions comparable with the distances between the centres of the atoms of which the material universe is built up; and

Digitized by Google

there is no reason to suppose that we have here reached the limit of frequency. It is known that the action of thought is accompanied by certain molecular movements in the brain, and here we have physical vibrations capable from their extreme minuteness of acting direct on individual molecules, while their rapidity approaches that of the internal and external movements of the atoms themselves.

Confirmation of telepathic phenomena is afforded by many converging experiments and by many spontaneous occurrences only thus intelligible. The most varied proof, perhaps, is drawn from analysis of the sub-conscious workings of the mind when these, whether by accident or design, are brought into conscious survey. Evidence of a region below the threshold of consciousness has been presented since its first inception in the Proceedings of the Society for Psychical Research, and its various aspects are being interpreted and welded into a comprehensive whole by the pertinacious genius of F. W. H. Myers. Concurrently our knowledge of the facts in this obscure region has received valuable additions at the hands of labourers in other countries. To mention a few names out of many the observations of Richet, Pierre Janet, and Binet (in France), of Breuer and Freud (in Austria), of William James (in America) have strikingly illustrated the extent to which patient experimentation can probe subliminal processes, and can thus learn the lessons of alternating personalities and abnormal states. Whilst it is clear that our knowledge of subconscious mentation is still to be developed, we must beware of rashly assuming that all variations from the normal waking condition are necessarily morbid. The human race has reached no fixed or changeless ideal; in every direction there is evolution as well as disintegration. It would be hard to find instances of more rapid progress, moral and physical, than in certain important cases of cure by suggestion—again to cite a few names out of many—by Liébeault, Bernheim, the late Auguste Voisin, Bérillon (in France), Schrenck-Notzing (in Germany), Forel (in Switzerland), van Eeden (in Holland), Wetterstrand (in Sweden), Milne Bramwell and Lloyd Tuckey (in England). This is not the place for details, but the *vis medicatrix* thus evoked as it were from the depths of the organism is of good omen for the upward evolution of mankind.

Modern Observation of Elusory Phenomena.

A formidable range of phenomena must be scientifically sifted before we effectually grasp a faculty so strange, so bewildering, and for ages so inscrutable, as the direct action of mind on mind. This delicate task needs a rigorous employment of the method of exclusion—a constant setting aside of irrelevant phenomena that could be explained by known causes, including those far too familiar causes, conscious and unconscious fraud. The inquiry unites the difficulties inherent in all experimentation connected with *mind*, with tangled human temperaments and with observations dependent less on automatic record than on personal testimony. But difficulties are things to be overcome even in the elusory branch of research known as Experimental Psychology. It has been characteristic of the leaders among the group of inquirers constituting the Society of Psychical Research to combine critical and negative work with work leading to positive discovery. To the penetration and scrupulous fairmindedness of Professor Henry Sidgwick and of the late Edmund Gurney is largely due the establishment of canons of evidence in psychical research which strengthen while they narrow the path of subsequent explorers. To the detective genius of Dr. Richard Hodgson we owe a convincing demonstration of the narrow limits of human continuous observation. It has been said that "Nothing worth the proving can be proved nor yet disproved." True though this may have been in the past it is true no longer. The science of our century has forged weapons of observation and analysis by which the veriest tyro may profit. Science has trained and fashioned the average mind into habits of exactitude and disciplined perception, and in so doing has fortified itself for tasks higher, wider, and incomparably more wonderful than even the wisest among our ancestors imagined. Like the souls in Plato's myth that follow the chariot of Zeus, it has ascended to a point of vision far above the earth. It is henceforth open to science to transcend all we now think we know of matter and to gain new glimpses of a profounder scheme of Cosmic Law. An eminent predecessor in this chair declared that "by an intellectual necessity he crossed the boundary of experimental evidence, and discerned in that matter, which we in our ignorance of its latent powers, and notwithstanding our professed reverence for its Creator, have hitherto covered with opprobrium, the potency and promise of all terrestrial life." I should prefer to reverse the apophthegm and to say that in life I see the promise and potency of all forms of matter.

In old Egyptian days a well-known inscription was carved over the portal of the temple of Isis: "I am whatever hath been, is, or ever will be; and my veil no man hath yet lifted." Not thus do modern seekers after truth confront nature—the word that stands for the baffling mysteries of the universe. Steadily, unflinchingly, we strive to pierce the inmost heart of nature, from what she is to reconstruct what she has been and to prophesy what she yet shall be. Veil after veil we have lifted and her face grows more beautiful, august, and wonderful with every barrier that is withdrawn.

An Essay
ON
THE MARRIAGE OF THE UNFIT.[1]

BY HARRY CAMPBELL, M.D., B.S. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL.

THE fitness of two individuals to marry embraces two considerations—their fitness as regards each other and their fitness as regards the production and rearing of offspring. Fitness of the former kind implies mental suitableness and also, where there are no private means, the ability of the one or the other to make the necessary provision; except when this is necessary physical health, desirable though it may be, is not an essential. There may be a "marriage of true minds" without it. It is not this kind of fitness which I propose to discuss, nor the ability of parents to rear children—i.e., properly to provide for and educate them, which is a separate question altogether and a very wide one—but rather the fitness to produce children who shall reach a certain level of mental and bodily excellence.

When men come to understand the potency of heredity the question of marital fitness will receive more attention, and they will begin to realise that the responsibility of making a life is scarcely less tremendous than that of taking it. As it is, one of the last things that occur to a marrying couple is whether they are fit to be represented in posterity. I know of few things more remarkable than the extreme self-complacency of human beings (and these often the most unfit) in this respect. Yet even as things now stand the physician is not infrequently called upon to decide whether individuals are fit as regards the production of children, and in view of the enormous responsibility thus thrown upon him it behoves him to be ready with a well-formed judgment in such cases. That they will come before us more and more in the future is to be both hoped and expected, and it is with the view to help to create a proper public opinion on these matters that I bring this subject before the profession.

In order that we may gain a philosophic insight into our subject we must understand the mode in which the human race is evolving and the part which heredity plays in shaping structure and causing disease.

We have still much to learn concerning the factors which determine animal evolution, but almost all are agreed that the principle of the "survival of the fittest" plays a predominant part in it. While it is a fact that the environment tends to mould the organism adaptively, in such a way, namely, that the latter becomes adapted to the environment, it seems very doubtful whether the direct action of the environment plays a decided part in animal evolution, because environmental mouldings (as we may term them) do not appear to be inherited. At any rate, no unmistakeable instance of the inheritance of an acquired character has yet been observed. It is therefore probable that organic evolution does not take place, or takes place only in a very slight

[1] Founded upon a paper read before the Watford Medical Society on April 1st, 1898.

Digitized by Google

degree, by a summation through successive generations of environmental mouldings. I need scarcely say how unwillingly one comes to this conclusion, for the old Lamarckian school, of which Herbert Spencer is the ardent apostle, held out the promise of great things. What might we not achieve by the continued inheritance of beneficial acquisitions? But this dream, so fondly clung to by our grand old thinker, is apparently but a dream, and it would seem that we must look for progress, not by direct equilibration, as he terms it, but by indirect, in other words by natural selection. Now this selection is of two kinds (*a*) sexual, of which I do not propose to say anything here save that the whole question of marrying is one of proper sexual selection, and (*b*) natural selection commonly so-called, or the survival of the fittest. Since animals tend to increase in geometric ratio, and since there is only room for a certain number, a struggle for existence ensues resulting in the survival of the most fit. Any animal possessing an attribute giving it an advantage over its fellows tends to be selected, and seeing that this beneficial attribute tends to be inherited, it is clear that a species may in this way be considerably modified in the course of several generations, just as happens in the case of the artificial selection practised by breeders of domestic animals.

The tendency of organisms to increase in geometric ratio is not, however, the only cause of natural selection. In the first place the environment is always changing, and this involves the continued readjustment to it of successive generations, by a survival of those individuals varying in suitable directions. But even were the environment unchanging, and were there no geometric increase, natural selection would still be needful in order to maintain adaptation owing to the law of deterioration. Natural selection, in short, has not done its work when it has achieved adaptation to a certain environment; its continued operation is needful in order to maintain a certain level of excellence, otherwise racial deterioration must ensue. Natural selection thus operating has been termed "panmixia." The offspring of even the most perfectly adapted parents are not all alike, but vary round a certain standard of excellence. Some fall short of it, and these require to be weeded out if the standard is to be maintained. Take as an instance the case of eyesight. In order to maintain this at a high standard there must be a continual elimination of individuals with defective sight. Among savage peoples even moderate degrees of short sight place the individual at a great disadvantage in the hunt and the fight, and tend to his premature death, thus preventing him from leaving progeny with the like defect. And what is true of the organs of sight applies to all the organs of the body—they are all liable to fall short of the standard of excellence, and panmixia is needful to the maintenance of that standard.

The tendency of species to increase in geometric ratio, the changeableness of the environment from generation to generation, and the occurrence of variations which fall short of the standard of excellence—these, then, are the factors which start the operation of natural selection. The first of them has little direct effect upon selection among civilised communities, since in their case food is placed within the reach of practically all, and those unable to procure food for themselves do not die as they would under more primitive conditions; but elimination from other causes is still busily at work among us. *Every death not due to accident or old age is really the elimination of an unfit variation*, and occurring before the end of reproductive life falls under the category of natural selection.

A word as to elimination due to changing environment. We are surrounded by vast armies of pathogenic organisms. Did they but remain unchanged we should sooner or later become adapted to them (as we should to any environment not fatal to the entire race) by the continued elimination of those of us least able to resist them; but these organisms being living are ever varying like ourselves and adapting themselves to new conditions, and consequently we never can become adapted to them all. We may possibly succeed in becoming adapted to some species and in starving out others, but depend upon it mankind will always be liable to germ diseases, let nature strive how she may to bring about adaptation to the organisms causing them, and we may be sure that untold millions will be sacrified in the attempt.

Next as to elimination by panmixia. The wonder is, if we come to think of it, not that it should operate, but that its operation should not be much more stringent than it actually is. Think for a moment of the marvellous complexity of the human organisation. Take any limited branch of physiology, make a life-long study of it, and every day will increase your wonder at the intricate adjustment of means to ends. Whether we study the physiology of the heart and vascular system, of phagocytes, or of sugar metabolism, or whether we contemplate the mysterious cerebral processes which underlie the operations of mind, we shall be equally impressed with the fact; and when once imbued with it we can only marvel that our hearts and vaso-motor systems, our phagocytes, sugar-forming organs, and brains serve us so well as they do, and that more of us do not suffer from palpitations, flushings, defective phagocytosis, diabetes, and insanity than is actually the case. How is this high level of excellence maintained? The answer is, By panmixia. If panmixia is needed in order to keep the several parts of the eye so nicely adjusted as to render accurate accommodation possible, must it not also be necessary in order to maintain the same level of excellence in respect of the cardio-vascular system, the phagocytes, and the tissues which subserve the glycogenic and kindred functions? As a matter of fact, defects in these systems constantly occur: a certain number of people do get serious heart disturbances, do get diabetes, do suffer from defective phagocytosis, and do go mad, and all such tend to get eliminated by the action of panmixia. The defects may, however, not be sufficiently great to lead to death. Many suffer from wretched health even when placed under the most favourable conditions. I am thinking especially of the large army of neurotics and hypochondriacs who, though life is but a misery to them, yet do not die and who thus escape the operation of panmixia. Nevertheless, it cannot but be supposed that under more primitive conditions it would operate among them.

This leads me to refer more at length to the interference with the operation of natural selection among civilised communities, for though, as I have said, natural selection is actively operating among them, it is of course to a large extent interfered with. Many lives are saved which would otherwise succumb through incapacity to cope with the environment. If every individual had to provide for himself, a large number would succumb who now live by the sufferance of their fellows. Some would succumb through not having sufficiently keen senses—hearing, eyesight; others through being crippled in their limbs; more from general weakness; others again from strangulated hernias, ovarian cysts, and so forth. These are now in numberless cases saved, and are thus enabled to have children who tend to inherit the like defects. Hence it follows that these defects are continually increasing among the civilised, and that the level of physical perfection among them is lower than among primitive communities, and if the present state of things continues, it must go on getting lower still.

I am tempted here to refer briefly to another interference with the operation of selection among the civilised. Among primitive communities polygamy generally prevails. Those members of a savage tribe who by their mental and physical superiority are able to raise themselves to the rank of chiefs secure the largest number of wives and leave the largest number of children to inherit the paternal excellences. Now while as a sociologist I am dead against polygamy, as a biologist I confess (at the risk of being accused of regarding humanity from the point of view of a stud-groom, as some one has put it) I cannot but regret its complete abolition. I would like to see our giant intellects and champion athletes leave a numerous progeny.

To turn now to the question of heredity. It is very necessary that we should understand its potency. The structure of an individual depends almost wholly upon it. The power of natural selection to mould a species presupposes its influence, for it assumes that the individual "selected" will transmit his peculiarities to his offspring. Let us ever remember that what we are, whether fair-skinned or dark-skinned, long-nosed or short-nosed, big-brained or little-brained, depends essentially upon our parentage. The influence of heredity in disease is vast, much greater, in my opinion, than must medical men deem it to be. In the text-books we are told that one disease is hereditary, 30 per cent., another 10 per cent., while a third disease is not hereditary at all. Not hereditary? I maintain that all diseases are hereditary: *you cannot eliminate the influence of heredity* from any disease, and I will prove it. What is disease? It

Digitized by Google

is abnormal life. And what is life? It consists of an interaction between the individual and his environment; therefore disease is an abnormal interaction between the two. It follows that you cannot possibly eliminate the part played by the individual from the causation of any disease, since it is *his structure which determines whether he shall or shall not react abnormally to a given environment*. Now his structure is essentially determined by heredity. I have therefore proved my point. This is no mere logical quibbling but a practical fact. I will test my position by taking a disease with which most people will probably say heredity has nothing at all to do—the wheal caused by flea-bite. This affection depends upon the morbid interaction of the host and the specific environment constituted by the poison with which the parasite inoculates him. As everyone knows, the liability to be flea-bitten and the tendency to suffer from wheals when thus bitten, differ greatly in different individuals. Some suffer little or not at all in this way; others grievously. Upon what does this difference depend? It depends upon differences in the organisation or structure of the host, and these differences are essentially determined by heredity. Hence all parasitic diseases, from a flea-bite to pulmonary consumption, from typhoid to malignant tumour, are hereditary. Such diseases depend upon defect in the organism as regards some specific environment, but others, such as chronic Bright's disease, diabetes, ovarian cyst, strangulated hernia, may occur independently of any specific environment, and it is obvious that these are *a fortiori* hereditary.[2]

To reiterate briefly the chief conclusions we have arrived at. There seems good reason to believe that organic evolution proceeds essentially by a survival of the fittest, and that all further evolution of man must take place essentially by the operation of this process. Natural selection is needful not only to *attain* adaptation of the individual to his environment but also to *maintain* it. Structure is chiefly determined by heredity, and seeing that disease is a morbid interaction between the individual and his environment and that his structure determines whether he shall or shall not react abnormally to a given environment, it follows that the factor of heredity cannot be eliminated from the causation of any disease.

We are now in some sort of a position to answer the question: Who are unfit to marry and have children? A question I can only very briefly answer in a paper like the present. We have seen that panmixia is largely interfered with in civilised communities, with the result that racial deterioration must inevitably be in progress, and will disastrously continue unless some new means is discovered by which man's present level of adaptation to his environment can be maintained. Happily, we have such a means to hand, and it is from among those very forces of progress wherein, as we have seen, arises his danger, that his safety also is to be found. For the leavening influence of high ideals for nearly 2000 years has had its effect, and modern progress, modern civilisation, tend more and more consciously or unconsciously, and whether we recognise it or not, towards altruism; it has already widened out man's conception of the duty he owes his neighbour until that duty has come to mean, to those at least who "feed the high tradition of the world," the service of humanity at large, and more enlightenment as to his undoubted responsibility to posterity will show him that that service does not end with the present generation but reaches forward to a future to which we can set no limits. Fortified with the conviction that generations yet unborn have also a claim upon him, a man could of his own free choice do far more than the blind working out of natural laws has ever done, or ever can do, to stamp out the tendency to disease and to perpetuate a healthy race. For all that is needed to enable panmixia to proceed as beneficially as ever, and that without the ruthless destruction of the unfit which obtains when natural selection works unchecked, is for those who have defects *which under natural conditions would lead to annihilation* to forbear to procreate. As beneficially, did I say? Nay, very much more beneficially, for not only could those who are already marked by disease refrain from marrying, but those also who as judged by their family history are likely to become ultimately the victims of serious disease. And if it be urged that such a self-denying ordinance presupposes a higher ethical development than the generality of men have at present attained, that by no means disproves my contention; it only proves that much has yet to be done to get a sound public opinion, a sensitive public conscience, on these matters, such an opinion and such a conscience as I hold it to be one of our first duties to strive to create. Meantime, I doubt much whether the renunciation would be felt to be so very great if men's minds were trained to realise all the issues that are involved, and if it were plainly shown, as it might be, that the sum total of human happiness would be increased by it. What I do recognise is that it must take time for society to get out of the old grooves of thought, sanctioned by almost the whole of our current fiction, as to marrying and giving in marriage, and that while it is getting out of them there must be at times personal suffering, stress and conflict where strong feeling is involved. But all progress is obtained at some sacrifice, the first steps in a reforming movement nearly always cost someone dear, and I can imagine a state of society gradually evolving out of this transition period in which there shall be such a sound healthy view of the responsibilities of marriage that the idea of any union that would be at all likely to involve the survival of the unfit would not be entertained for one moment, and where consequently, there would not be felt to be any renunciation to make, any more than there is now in keeping within the prohibited degrees of the prayer-book and not marrying one's grandfather or grandmother. It is a notable and I think hopeful sign of the times that in a recent novel by Robert Buchanan, in which the reader is introduced to the twenty-first century, he assumes that by a careful elimination of the unfit a state of physical perfection has been achieved. The markedly unfit are disposed of in the chamber of Euthanasia and man and woman may not "under any circumstances come together in lawful wedlock without a certificate of physical perfection from the Holy Office of Health." Now though the time is far yet when men will submit to State coercion in such matters, it is not therefore too soon to urge their responsibility upon them, and everything that will awaken them to it, whether from the press or the pulpit, is to be welcomed.

Let us now consider under what circumstances the physician ought to use his influence to prevent marriage. In certain cases there can be no doubt as to the course he should take. Such serious diseases as pulmonary consumption, organic heart disease, epilepsy, insanity, diabetes, and chronic Bright's disease, are obvious bars to m rriage. Not only the present existence of any one of these diseases, but the having had it and recovered from it, would in my opinion constitute unfitness. The same restriction applies, I think, to rheumatic fever (certainly if there has been more than one attack) and to most cases of acute Bright's disease not due to scarlet fever, especially when the inflammation has been of more than two months' duration.

There are other disorders equally serious in themselves but the having suffered from which is not usually regarded as a bar to marriage. I allude to all those cases of non-accidental disease in which life is saved by the surgeon's skill. Most if not all individuals of this class should be regarded as unfit for procreation. Take the case of a person with strangulated hernia or ovarian cyst. In a less artificial condition of existence such a one would be weeded out as unfit and thus prevented from transmitting to others the like defect. Let us use all the means at our command to rescue such from death, but it must be upon the clear understanding that no children shall be born to them afterwards. Think of the millions and millions of women suffering from ovarian cyst whom nature has in the past sacrificed with a cruel kindness, in order to keep up a certain level of ovarian fitness in the race. These are practically all saved now in civilised communities, with the result that the percentage of ovarian cysts is necessarily increasing. It can only be because medical men do not realise the potency of heredity that they sanction the propagation of children by women whose lives have been saved in this way.

In cases of the class just referred to there can be no doubt about our course, but in other and kindred cases we may find it more difficult to decide what to do. We cannot rely on the rule—in the main a safe one and which I believe should always form the basis on which our own judgment rests—that those with some defect which under primitive conditions would lead to destruction should refrain from marriage. To take an example, a person with a bad error of refraction can be made to see well with glasses and may become a very useful citizen, and although we cannot but regard with regret and misgiving the increasing defect of vision which is

[2] I have discussed the influence of heredity in disease in my work, "The Causation of Disease," p. 318, *et seq.*

Digitized by Google

taking place in consequence of the interference with panmixia in this one single class of cases only, it would need more boldness than most of us possess to advise a person to refrain from marriage on account of such defect alone. We should be merely laughed at. With congenital defect of hearing the case is different. There we can speak with authority: none such should procreate.

I now come to a particular class of disorders which I think should beyond almost all others be regarded as a bar to marriage. I mean functional disorders of the nervous system. The highly sensitive are not suited for this hard world. Its strenuous conditions call for men of iron nerve and stout hearts. I fear it must be acknowledged that as regards happiness—which at any rate from the purely physical point of view may perhaps be fairly looked upon as our being's end and aim—the fine animal with little imagination and a good thick skin has the best time of it here—is the most truly "fit." It may be that such a one cannot rise to the same heights of happiness as his more nervous and imaginative brother; but, on the other hand, he is incapable of sinking into the same depths of wretchedness. The future has no terrors for him, for he has no imagination to depict it; he lives in the enjoyment of the present, and even when afflicted with the gravest organic disease he suffers very little as compared with people of weak nerves, whose lives are often one long-drawn-out misery. In this latter class I include not only those who suffer from continual headache, noises in the ears, depression of spirits, and so forth, but the hysteric and hypochondriac class also. To the neurotic man as well as to all of these I should say, "Remain single." He is often advised to marry on the ground that wife and children will draw him out of himself, and so far the advice is doubtless good, but I fail to see what right we have to sacrifice the prospective wife and children. I have seen too much home misery caused by neurotic parents to connive at such an arrangement.

In testing an individual's fitness to marry we have to consider not only his past history and his present state, but his probable future as judged by his family history, and this enables us, as already observed, to be more searching than even natural selection. Among the many evils which it would be possible greatly to diminish, if not to eradicate, by obeying the warnings furnished by family history are apoplexy and premature senility. Seeing that deaths from these causes do not as a rule occur until after the procreatic age—i.e., until after the individual has had the opportunity of leaving a full complement of children—such deaths leave little direct impress upon the race. In regard to the staving off of senility I hold it to be well within our province to attempt to do so. The fate of the man in his sixties who, in the zenith of a successful career, or having just settled down to well-earned rest after an anxious and laborious life, is struck down by apoplexy, or who suffers from a general senile breakdown, is surely a tragic one, and I contend that we should wage hot warfare against such occurrences. Some there are whose blood-vessels degenerate, whose hair turns grey, and whose tissues generally show a tendency to senility while yet in their thirties; and on the children of such, especially those who "take after" the prematurely senile parent, we should for the most part urge abstention from marriage. For it is quite remarkable how individuals as they grow old imitate the old age of their parents, sometimes of the one, sometimes of the other. How often does it happen that the young have occasion to criticise the testiness, the ill-nature, or the selfishness of the old. It seems to them quite impossible that they can ever be the same themselves, and yet as the years roll on it too often happens that all the weaknesses of the parent recur with painful exactitude in the child. Indeed, the exactness with which the individual repeats the life history of his progenitors is freshly impressed upon me every day of my life and I often find myself involuntarily forecasting the future of the child by reference to the condition, mental and physical, of the parent. I have in my mind a case in point. Mr. and Mrs. A. are between forty and fifty years of age. Each became decidedly grey before thirty, and as in all such cases each is highly neurotic and has within recent years developed several nervous symptoms. Mr. A., indeed, shows signs of a complete nervous breakdown. Now there are seven children of this marriage from eighteen years of age downwards and they are what would be called remarkably "fine" children; yet it is as certain as anything can well be that the majority of them, if not all, will like their parents become prematurely grey and neurotic. To look at them now without any reference to their family history no one would anticipate this for a moment, but judged in that light it is no mere idle fancy but almost a certainty; and if we were able to prevent marriage in their cases we should be helping towards the elimination of a prematurely senile and neurotic type.

To return, in conclusion, to what I have already touched upon—the difficulty of a practical application of these views. As a general reply to the objections that few are capable of the sacrifice of enforced celibacy where the affections are engaged, and that any interference with marriage on the grounds above given is an undue infringement of the liberty of the subject, I would observe that the life of the individual living in a civilised community is one long-continued self-restraint and that each such individual has very much less freedom of action than is generally supposed. Turn where he may he will find his actions restricted, for, being part of a highly complex social machinery, elaborate rules of conduct are necessarily imposed upon him; mere prudence indeed, compels a man constantly to restrain his natural impulses. And surely when it is realised what are the tremendous issues at stake we may take a higher ground than the ground of mere expediency and appeal to the sense of duty; but it were a very poor and inadequate conception of duty which could content itself with the fulfilment of obligations to the living heedless of those who shall come after. Theft and murder are considered the blackest of crimes, but neither the law nor the church has raised its voice against the marriage of the unfit, for neither has realised that worse than theft and well-nigh as bad as murder is the bringing into the world, through disregard of parental fitness, of individuals full of disease-tendencies. This has been left to our own profession, and we shall be unworthy of its traditions if we do not, each of us in his own particular sphere, strive to bring nearer the day when, not in a heritage of woe but of blessing, the deeds of the fathers shall be visited upon the children unto the third and fourth generation.

Wimpole-street, W.

THE CAUSES OF URINARY FEVER AT THE BEGINNING OF CATHETER LIFE.

By C. MANSELL MOULLIN, M.D. OXON., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL; EXAMINER IN SURGERY AT THE UNIVERSITY OF OXFORD.

MANY years ago Sir Benjamin Brodie drew attention to the very serious symptoms that not infrequently follow the withdrawal of residual urine from the bladder in cases of enlargement of the prostate at the beginning of what has been called "catheter life." Since that time the symptoms have been described by Sir Henry Thompson and by many othe and by nearly every one they have been attributed to the suddenness with which the change is made from the natural and usual mode of micturition to the artificial method. Removing the whole of the residual urine at once and on every occasion of catheterism is most injurious during the first few days. "If the patient has been in the habit of retaining perhaps a pint of urine, or even more, after he has made water it is a serious change for the bladder to be suddenly and completely emptied two or three times a day. The organ soon becomes irritable, the urine is charged with pus, the patient loses appetite and becomes feverish, and there is sometimes considerable danger to life. The rule under such circumstances is to proceed cautiously. Instead of removing the entire quantity leave some urine behind, and thus a compromise is made between the exigencies arising in this condition of the bladder and the usually absolute rule that it should be emptied. Draw off half or only two-thirds of a pint; you will thus relieve the organ partially and in the course of a week or sooner you may gradually accomplish the entire emptying of the bladder and all will probably go well. And it conduces greatly to success to permit no out-door movement to such a patient, but to confine him to his room, in a warm temperature if the weather is cold, or even to his bed for a few days."[1] In the light of the results arrived at by recent

[1] Sir H. Thompson: Clinical Lectures on Diseases of the Urinary Organs, sixth edition, Lecture x., p. 56.

Digitized by Google

bacteriological researches into the causation of cystitis and urinary fever, it seems to me not altogether inopportune to inquire how far the generally received explanation is correct.

So far as the broader features are concerned the symptoms that present themselves in these cases are remarkably uniform. They do not begin at once. Nearly always some few days elapse before there is anything to excite suspicion. Then the urine becomes cloudy though it may still maintain its acid reaction. A small quantity of albumin, more than can be accounted for by the amount of pus that is present, makes its appearance. Under the microscope there are a few hyaline casts, perhaps a blood corpuscle or two, numerous pus corpuscles, and myriads of bacteria. The specific gravity is lower than it ought to be, and lower than it was before the catheter was used. The total amount passed in the twenty-four hours may either increase until it is as much as seven or eight pints, or diminish until it scarcely reaches twenty ounces. There is seldom any definite rigor but there may be numerous slight chills. The pulse grows more rapid and feeble. The tongue becomes red and dry. There is complete anorexia. Delirium sets in at night, and in a considerable proportion of cases the symptoms rapidly grow worse and worse until, at the end of a few days, the patient sinks into a semi-comatose condition from which he seldom rallies. Post mortem there are all the signs of recent acute cystitis and pyelonephritis. The mucous membrane lining the pelvis and calices of the kidneys, the ureters, and the bladder is swollen and stained by old and recent hæmorrhages, and here and there a thin layer of pus is adherent to it. The pelvis and the ureters are dilated, the apices of the pyramids are eaten away, the cortex is shrunken and hard, the capsule is adherent, and in places between the tubules are minute collections of pus differing in shape and outline according to the anatomical arrangement.

It must be admitted at once that there is a great deal both in the clinical history and in the post-mortem appearances that not only cannot be explained by, but is entirely inconsistent with, the hypothesis of too rapid evacuation. The symptoms do not begin at once, even if the bladder is emptied completely. (I do not include those cases in which fatal syncope is caused by rapidly drawing off a large quantity of residual urine from the bladder when the patient is standing upright; such cases belong to an entirely different class.) The symptoms often do not set in for four or five days. They cannot therefore be explained as the result of shock or of inhibition of the vasomotor nerves of the kidneys. They do not occur when an aspirator is used to relieve retention of urine in prostatic enlargement, even if it is used four or five times, provided always that the patient regains the power of voluntary micturition when the congestion has passed away, and that no catheter is introduced. On the other hand, if the kidneys are sclerosed exactly the same symptoms may occur without any residual urine at all, if a catheter is passed or any operation, such as lithotrity, performed in the bladder; and it cannot be denied that the cause assigned is not reasonably sufficient. Inflammation of the bladder and kidneys may be caused by various agents, but there is absolutely no evidence to support the view that evacuation of the urine is one of them. The wall of the bladder, it is true, is always in a state of atony in such cases, but the pressure of the abdominal viscera from above and the weight of the abdominal wall are more than sufficient to compensate for the loss of tension due to the evacuation of a few ounces of urine. Suppuration, which is invariably present in these cases, both in the bladder and the kidneys, is still more unintelligible. No account whatever is taken of the profuse bacterial growth in the urine and the tissues of the urinary organs. The beginning of it all, the earliest sign that there is anything wrong, is cystitis. It may not appear to be very severe, but it is always there and is always purulent, and caused, therefore, by pyogenic organisms. The symptoms may be slight (probably because the neck of the bladder is not so much involved as the post-prostatic part); the urine may retain its acid reaction; and there may be but little pain and strangury; but there is a distinct floating cloud in the urine, and if the urine is allowed to stand or, better, if it is placed in a centrifugal machine, this cloud condenses into a greyish deposit, which under the microscope consists almost entirely of pus corpuscles and bacteria. The deposit is not mucus. As Traube[2] and Cohnheim[3] long since pointed out there is no such thing as catarrhal cystitis. Cystitis is always purulent. Mucous glands do not exist in the bladder and the epithelium that lines it is never converted into mucus secreting cells as it is in the intestine. The deposit that is usually spoken of as mucus either consists of detached epithelial cells with a few pus corpuscles, or else is simply pus that has been converted into a glairy mass by the alteration in the reaction. If the urine is centrifugalised so as to concentrate the deposit pus corpuscles and bacteria can always be found. Putting aside those forms of inflammation of the bladder that are due to chemical reagents (such as cantharides) and specific organisms (the tubercle bacillus, for example, or the bacillus of typhoid fever, or the gonococcus), cystitis is always purulent, and the immediately exciting cause is invariably the access of pyogenic organisms. And, finally, the symptoms themselves do not present more than a very vague and general resemblance to those that are characteristic of uræmia and suppression of urine. They are essentially the symptoms of a subacute form of septicæmia occurring in a person whose health is broken down by chronic renal degeneration. Comparing them with the results shown by the recent experiments of Albarran and Hallé in France and of Rovsing and Melchior in Denmark, there is no doubt that they are caused by the growth of septic organisms in the urine and the walls of the urinary organs, and that they are to be prevented, not by slowly and gradually reducing the amount of residual urine, but by proper attention to the principles of aseptic catheterism.

The micro-organism that is most frequently present is the bacterium coli commune. It was first described in the urine by Clado[4] as the "bacterium septicum," next by Albarran and Hallé[5] as the bacterium pyogenes. Then almost simultaneously its identity with the bacterium coli was demonstrated by many observers. Albarran and Hallé found it in 47 cases out of 50, and by itself (pure) in 15. Albarran alone found it in 23 out of 25 and pure in 16. Morelle[6] found it in 13 out of 15 and pure in 6, and Melchior[7] found it 24 times out of 35 and pure in 17. In the last two years I have myself examined a very large number of cases and have rarely been able to find it. The next most common is a form of streptococcus, probably identical with the streptococcus pyogenes, and like this organism especially associated with diffuse forms of suppuration and phlebitis; and then one which Melchior identifies with the proteus of Hauser, exceedingly important from the energy with which it causes decomposition of urea. After these there comes a host, as many as thirty different varieties having been described; but probably many of them are the same under different names, and in any case their importance is very much less than that of the three which I have mentioned.

These organisms are always present in inflammation of the bladder. Cystitis (with the exceptions I have mentioned) cannot occur without them. Normally they are not present in the urine or in the bladder. Healthy urine obtained from a healthy bladder with proper precautions to avoid contamination is perfectly sterile. Cultivations give no result. No micro-organisms can be found by the microscope, even after the persistent use of the centrifugal machine. The urine in cases of intra-peritoneal rupture of the bladder does not give rise to peritonitis until secondary changes have developed from the injury sustained by the bladder itself. If the operation is strictly aseptic the urine does not prevent union by the first intention in cases of suprapubic cystotomy. Union by the first intention has even been known to occur after lateral lithotomy. In animals the urine, both that which has descended into the bladder and that which remains in the pelvis of the kidney, is sterile for some time after death; and the few results that have been obtained under similar circumstances in the case of man point in the same direction. Nor does this arise from any resistance offered by the urine to the growth of pathological organisms, or to the fact that the urine never becomes infected. Urine is an excellent nutrient medium, both for those organisms that grow in the presence of air and for those that do best without oxygen. The explanation is that so long as the organs that secrete the urine and retain it are healthy, organisms have no chance of growing in it. They can get into the bladder through the kidneys—for it is well known that the microbes of many infective disorders are discharged in this way—or they may enter it by the urethra, especially

in the case of women, or by some accidental route. Guyon,[8] for example, has published a case in which for weeks together a stream of pus, loaded with virulent micro-organisms, poured through a patient's bladder; but so long as the bladder is healthy and working under healthy conditions, the organisms, no matter what their nature or how great their number, are swept away by the continuous flow before they can take any hold and the contents of the bladder remain aseptic.

The source of these organisms is the urethra: they exist there and in the neighbourhood of the meatus in profusion. Urine passed *per vias naturales* or drawn off in the ordinary way with a catheter is very rarely sterile. Nearly always under either of these conditions cultures may be obtained with ease If the glans penis and the prepuce are thoroughly disinfected beforehand and if an irrigating catheter is passed down to the neck of the bladder and the whole of the canal that lies in front of this is washed out from behind with a strong solution of boric acid, sometimes, then, a perfectly sterile specimen can be obtained. But the only simple method that can be relied upon is that which has been devised by Melchior[9] or a modification of it. Melchior employs a double catheter, one tube lying inside the other. The outer tube has a terminal orifice which is closed by means of a rubber film. The inner tube lies inside this and when the outer is passed down to the neck of the bladder is pushed on through the film, rupturing it as it goes. In this way the inner tube is protected from contact with the micro-organisms that inhabit the urethra, except perhaps at the moment that it bursts through the film, and if the urethra has been washed out first and the instrument sterilised the result can generally be relied upon. The urethra, in short, is full of germs. What Melchior calls the urethral flora is most abundant. Every time urine is passed it washes some of them out and every time a catheter is passed it carries some of them in and, as might be imagined, no antiseptic that can be applied to the surface of the instrument is of the slightest use. If the antiseptic is weak it is no good; if it is strong it does harm by irritating the surface of the mucous membrane; and in either case it is swept off at once by the lips of the meatus or, at the farthest, by the mucous membrane an inch or two down.

Such is the state of things that exists during health. The bladder contains a variable amount of urine that is perfectly sterile. The urethra, especially the anterior part of it, harbours a profusion of septic organisms. The sphincter at the apex of the prostate is the barrier, and so far as the male sex is concerned is capable of preventing the germs getting in of themselves. Whether there is any enlargement of the prostate or collection of residual urine, so far makes no difference. But there is an immense difference as soon as a catheter is passed. Unless special precautions, such as those devised by Melchior, are taken, some of the septic organisms are certain to be carried in by the catheter. It is impossible to prevent it. If the bladder is healthy and capable of emptying itself completely no harm results, the organisms do not get the chance of growing. But on the other hand if the bladder is not capable of emptying itself as it should, if there is any urine left habitually, at once the bacteria begin to increase and multiply, and very soon they spread into the epithelial layer and set up septic cystitis. It is the entrance of these bacteria into the bladder in cases of enlargement of the prostate and residual urine that causes the cystitis, and not the evacuation of the residual urine.

This, however, is not quite all. Residual urine not only favours the occurrence of cystitis by providing a supply of nutrient material in which the germs can grow, but it seems as if it had the power as well of weakening the resistance of the tissues that form the wall of the bladder, so that the bacteria can penetrate more easily. It is true that under certain conditions the bacterium coli may acquire such a degree of virulence as to excite septic inflammation in a healthy and uninjured bladder[10]; but this is not the rule. In general there must be some additional predisposing cause, although be it said, this need often only be of the slightest description. An attack of congestion such as is so common in old men with enlargement of the prostate, bruising the wall of the bladder with a catheter, cold applied to the surface of the abdomen, or temporary retention of urine, is quite enough. The experiments performed by Melchior upon rabbits prove that in them six hours' retention is sufficient to turn the scale. A culture which injected into a rabbit's bladder with the urethra open does no harm, causes intense cystitis if the penis is tied. And Bary[11] has shown that the result is the same if the injection instead of being thrown into the bladder, is thrown into the auricular vein, so that the organisms reach the urine, not directly but through the kidneys. In men with enlargement of the prostate the condition of partial atony that is always associated with residual urine is quite sufficient as the predisposing cause. The nutrition of the epithelium suffers as much as that of the muscular coat; it loses the power of offering an effectual resistance and the septic organisms penetrate more easily and grow more freely.

A striking example of the way in which residual urine prepares the way for cystitis (by its presence, not by its absence) is not uncommonly met with in women. Purulent cystitis, in which the urine is loaded with micro-organisms, sometimes breaks out quite suddenly in women after severe operations, when they are kept lying upon their back for many days together. The muscular power of the bladder is not so great in them as it is in men, for it has not so much work to do, and partly for this reason and partly from the difficulty they experience in micturating when in the recumbent position, women under these circumstances frequently do not empty their bladder thoroughly until they sit up. In other words, there is in them a condition of partial retention similar to that which is present in so many old men with enlargement of the prostate, with, however, one very decided difference. In women it is comparatively easy for germs in the region of the meatus urinarius (where they abound in singular profusion) to gain entry into the bladder; in men it is not. Consequently in the former cystitis without catheterism is common, both conditions are fulfilled, the entry of organisms and the presence of residual urine. In the latter it is altogether exceptional. Fortunately in women the very conditions that render an attack of cystitis so easy are equally energetic in causing it to disappear as soon as the position in altered and they sit upright. Cases of stricture of the urethra in men not uncommonly illustrate the same point. I have known a patient go about for months with his bladder half-way up to his umbilicus and his urine dribbling away from him without a sign of cystitis. The urine when it was drawn off was acid and perfectly clear. In three days' time it was turbid and full of organisms, carried in undoubtedly by the instruments used to dilate the stricture. The bladder was in a state of atony from long-continued over-distension and unable to empty itself, there was a certain amount of residual urine, the epithelial lining was incapable of offering active resistance, the germs spread rapidly into the wall of the bladder, and a very severe attack of cystitis followed. And essentially the same thing happens when the expulsive power of the bladder has been lost in cases of paraplegia due to injury or disease of the spinal cord. The bladder is not emptied thoroughly. Sooner or later germs are carried in by the catheter and cystitis follows. The length of time that elapses from the date of the paralysis to the beginning of the cystitis is a measure of the care that is taken in the treatment of the retention.

One of the chief reasons, I believe, why so little attention has been attracted to the real source and importance of the cystitis that occurs after the removal of residual urine is that the inflammation has not been regarded as septic, because the urine has not undergone ammoniacal decomposition. Urine is often thought to be free from organisms that can do any serious harm, if it is only acid. One of the most valuable results of Melchior's work, and one that is thoroughly borne out by clinical facts, is that the worst forms of septic cystitis and urinary septicæmia may occur independently of ammoniacal decomposition with urine that is distinctly and persistently acid. Ammoniacal decomposition is a very grave addition in cystitis and still more in pyelonephritis, but it is by no means essential. Germs that live in acid urine can and do give rise to toxic products capable of causing intense septicæmia. Some time ago I removed through a perineal incision a small polypoid outgrowth from the region of the neck of the bladder in a patient aged fifty-eight years. The specific gravity of the urine was a little below what it ought to have been and there was a large amount of residual urine in the bladder, 12 oz. at least and sometimes more, but otherwise the patient was

in good condition. The operation was a short one and perfectly successful. As often happens in such cases there was a considerable amount of venous oozing afterwards (although the pedicle had been twisted off) and the blood coagulating in the prostatic urethra caused a good deal of straining. Two days later a rigor set in and from that time during the six weeks that the patient lived the temperature was never normal. No secondary deposits of any kind made their appearance. There was no pneumonia or joint affection, merely exceedingly irregular temperature with rapid emaciation and intense depression. The most noteworthy feature was the extremely offensive character of the motions. Their colour was almost black and the odour intolerable. Nor had any of the drugs that are usually regarded as intestinal antiseptics the least influence over them. There was no albuminuria and no sign of renal infection or of suppression. The quantity of the urine was good and the specific gravity was the same that it had been. Throughout the whole time the urine was acid but it was loaded with long, slender bacilli which, from my later experience in connexion with them, I have little doubt were the bacterium coli and from the intensely offensive character of the intestinal contents a peculiarly virulent form of it. During the straining that followed the operation it seems probable that some of these virulent bacilli were forced into the open ends of the veins at the neck of the bladder and caused general septicæmia. And there can be little doubt that the rigors that occur after internal urethrotomy and after operations upon the kidney involving the opening of large and deep-seated collections of pus (I have known a rigor set in after a pyonephrosis had been explored almost before the patient had been removed from the operating table), are due essentially to the same cause, either the toxic products of the organisms or the organisms themselves being forced into the circulation. On this point, however, there is no need to dwell. The virulent properties that the bacterium coli is capable of developing under certain conditions are well known; and Melchior has shown by experiments upon animals that the products of cultures in urine are as poisonous as those of cultures in broth and other media.

The septic pyelonephritis which is always present in cases that terminate fatally after the withdrawal of residual urine is the natural sequence of the septic cystitis. Perhaps it sets in all the sooner because the ureters are so frequently dilated and because their terminations in the bladder are so often covered with the deposit from the urine.

The injurious effect of the habitual presence of a large quantity of residual urine shows itself here, too, as well as in the bladder. The ureters, the pelvis and calices of the kidneys, and the substance of the kidney itself, suffer in a similar manner. Dilatation of the pelvis, and sclerosis and degeneration of the cortex and medulla, are inevitable in cases of long-standing residual urine. Whether the connexion is a mechanical one, in the same way that the connexion between residual urine and enlargement of the prostate is mechanical, or whether, as Albarran[12] believes, the renal degeneration is the product of septic organisms not sufficiently numerous or powerful to cause suppuration is beside the question at the present time. Degeneration is always present, and as in the bladder so in the kidney, the power of resisting the assault of septic organisms possessed by healthy tissues is impaired or lost. The septic organisms spread rapidly from the bladder up the ureters to the pelvis of the kidneys. Thence they work their way either by the lymphatics or through the intertubular spaces into the medulla and cortex, and whenever they are arrested they set up suppuration.

The immediate result is twofold. On the one hand, the function of the kidney is so much interfered with that there is defective elimination of urea and other waste products, sometimes amounting to suppression of urine. On the other hand, there is the more or less rapid absorption of the toxic products of these organisms—products which clinical and experimental evidence alike have shown capable of causing rigors and all the other phenomena of septic intoxication. But no matter which is the more prominent in any individual case it stands out clearly that both are due directly to the septic organisms that have found their way up from the bladder, and that these in their turn have been carried into the bladder from the urethra by catheters. The effect is the result, not of the withdrawal of residual urine rapidly or slowly, but of the introduction of pyogenic organisms (and especially the bacterium coli) under conditions that suit their growth to perfection.

Aseptic catheterism is one of the problems of modern surgery. It is impossible to deal with it fully now, and I will only mention the precautions which I have been constrained to adopt in cases in which there is a large amount of residual urine, and which, so far, have proved successful. All instruments must be disinfected first by boiling. The hands, the prepuce, and the skin of the penis must be cleansed as thoroughly with soap and water as if a surgical operation were going to be performed, and then sponged over with a solution of corrosive sublimate, 1 part in 5000. The glans and the meatus require especial care. An irrigating catheter is then introduced into the fossa navicularis and this part of the canal thoroughly washed out from behind with boric acid. Then the catheter is pushed on into the deep part and the process repeated. Finally Melchior's double catheter is introduced and the urine drawn off. In this way it is possible to obtain a very high degree of asepticity. The lubricant I prefer is lanolin, because it is readily soluble in water, kept aseptic by the addition to it of 1 part in 5000 of corrosive sublimate. Afterwards, and in the case of an old man with enlarged prostate, I try to enforce the same precautions as far as possible; but when catheters have to be passed at frequent intervals the disinfection of the hands, penis, and front part of the urethra will manifestly be never carried out each time. At the outside it will only be done night and morning, and often one has to be content if it is done thoroughly once a day. But catheters can be kept clean. Those made for me by Messrs. Maw, Son, and Thompson, as smooth and as polished on the inner surface as they are on the outer, which were described in THE LANCET of July 6th, 1895, will stand boiling day after day (if they are kept straight while in the boiling water and drained afterwards) and continued immersion in boric acid without injury. Each patient is provided with two of the glass catheter cases devised by Dr. Nicoll of Glasgow. One of these is filled with boric acid lotion for instruments that have been used; the other, provided with a rubber cork as well as a metal cap, is dry and aseptic. These cases are so arranged that they can be hung up in the patient's wardrobe, out of sight and out of dust. No catheter is used more than once a day. As soon as a catheter is withdrawn from the urethra it is dropped into the case filled with boric acid solution and left there. Once a day all the catheters are taken out, boiled for five minutes, and placed in the dry case until required. The plan is not perfect and I have no doubt is capable of improvement, but it works fairly well with an intelligent private patient who can be made to understand the necessity of observing strict precautions. Unfortunately they are not all intelligent, and in the case of a hospital out-patient such a complicated plan is out of the question. The best that can be done is to start such people as well as possible and hope that by degrees they will acquire a certain amount of immunity against the toxins they are bound to absorb. There is a little evidence to show that a certain degree of immunity may be acquired, but I am very sceptical as to its ever being sufficient in the face of a virulent growth, or when the bacterium coli is assisted by other germs such as the streptococcus and the proteus.

A SERIES OF CASES OF OBSTRUCTIVE DISEASE OF THE LARGE INTESTINE TREATED BY LATERAL ANASTOMOSIS—IN ONE CASE AFTER COLECTOMY.

BY G. H. HUME, D.C.L. DURH., F.R.C.S. EDIN.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

CASE 1. *Malignant growth at the splenic flexure of the colon; lateral anastomosis of the cæcum and the sigmoid by Senn's plates.*—In August, 1894, a man, aged seventy-two years, was admitted into the Newcastle Royal Infirmary, under the care of Dr. Drummond, suffering from obstruction of the large intestine. Symptoms of intestinal trouble had existed for a year and these at the time of admission had

Digitized by Google

become acute. The abdomen was much distended, the distended and loaded intestines being visible as an oblique ladder. The last motion, which consisted of only a few small scybala, was passed on August 1st, and thereafter signs of obstruction with vomiting became urgent. The patient was transferred to me for operation on August 6th. A constricting mass was found at the splenic flexure of the colon. This was bound down and surrounded by enlarged glands, so that any radical operation was impracticable. A lateral anastomosis was therefore made between the cæcum and the sigmoid, the bowel being first drained and washed out with boric solution. The incision in each portion of the bowel was an inch and a half in length and the junction was effected by Senn's plates and a surrounding row of Lembert sutures. A piece of omentum was wrapped round and fixed as an additional safeguard. Relief to all the symptoms was immediate. The bowels were well moved on the second day and afterwards daily. One of the bone plates passed on the fifth day and the other came away in pieces on the seventh day. He left the hospital on the eighteenth day after the operation expressing himself as feeling quite well, and he continued well throughout the ensuing winter. In the spring of 1895, however, he returned with a renewal of obstructive symptoms. The tumour had greatly enlarged and it now extended across the abdomen from left to right. An exploratory incision into the cavity was made, but nothing could be done to afford relief. He recovered from the operation and the wound being healed he left the hospital, but died soon afterwards.

CASE 2. *Stricture (probably non-malignant) at the hepatic flexure; three attacks of obstruction; lateral anastomosis between the cæcum and the transverse colon.*—The patient, a slight, thin man, forty-nine years of age, but looking older, was seen in September, 1895, with Mr. Galbraith of Gosforth. He had for several days vomited all his food and there had been no action of the bowels. The abdomen was distended and tender all over and the vomit was unmistakeably stercoral, but it was stayed by washing out the stomach and stopping all feeding by the mouth. Food was given by the rectum for several days and then a cautious return was made to stomach feeding. The bowels were in the end moved by enemata and convalescence went on satisfactorily. This attack, which was the first in which the patient was seen, was the third of a similar character which had occurred, the first being in 1887 and the second in 1891. As soon as his strength was sufficiently regained he was admitted into the Newcastle Royal Infirmary for operation. When examined upon admission a small hard nodule could be felt under cover of the outer border of the right rectus at the level of the umbilicus. The operation was performed on Nov. 25th, 1895, the abdomen being opened in the right linea semilunaris. The appendix was first examined and was found to be normal, but the cæcum was much distended, whereas the transverse colon when drawn down was found to be as markedly collapsed. Examination of the intermediate portion of the colon was hindered by extensive and firm adhesions. The cæcum was therefore opened and the finger passed up to a tight stricture which did not admit the finger-tip. From the lengthened history of the case—the first attack dating back eight years—and from the absence of any definite growth, it was judged that the stricture was non-malignant. The extent of adhesions would have made the removal of the affected part of the intestine difficult and tedious, and it was therefore resolved to short-circuit by anastomosing the transverse colon to the cæcum. This was done in the way hereafter described, a very free communication being made. The operation gave immediate relief to the abdominal discomfort which previously had been constant. Almost at once flatus was passed freely *per anum*. There was no sickness and therefore food was given by the mouth from the first. The bowels acted of themselves on the third day and recovery was rapid and uneventful. The patient left the infirmary on Dec. 23rd, when he was on full ordinary diet and quite relieved from all his symptoms. Since then he has continued well and has been able to follow his occupation, which involves much knocking about and irregularity of meals. When he was examined quite recently no induration or swelling of any kind was to be found in the abdomen.

CASE 3. *Malignant growth of the cæcum, anastomosis between the ileum and the ascending colon.*—A woman, aged forty-eight years, was admitted into the Newcastle Royal Infirmary in June, 1896, complaining of severe abdominal pains and stoppage of the bowels. On examination a hard fixed mass was found in the right iliac region. On June 11th the abdomen was opened and a growth apparently carcinomatous was found in the cæcum. The growth was irremoveable, and an anastomosis by lateral apposition was therefore made between the ileum and the ascending colon. The patient made a good recovery, and was quite freed from all symptoms of obstruction. She was last seen in October, 1896, when the growth had considerably increased, but although she still suffered from much pain the action of the bowels was regular and sufficient.

CASE 4. *Malignant disease of the cæcum; lateral anastomosis between the ileum and the transverse colon.*—In February, 1896, the patient, a man, aged fifty-three years, noticed a hard lump in the side which was painful on pressure, and there was constant pain in the right side, and much trouble from flatulence. For some time after his admission into the Newcastle Royal Infirmary (in June, 1896) his temperature ran high, suggesting the possibility of the swelling being inflammatory. The tumour extended to within an inch and a half of the umbilicus and downwards to Poupart's ligament. The edges were well defined except below and the skin was moveable over the tumour. The abdomen was opened beyond the margin of the tumour in the right linea semilunaris and the swelling examined. It was found to be a growth involving the cæcum, and not removeable. The ileum was connected by lateral anastomosis to the transverse colon. For a fortnight after the operation the patient went on well. The wound had healed and the dressings were removed. Then the temperature began to rise and he suffered from pain and distension. It was evident that peritonitis had set in, most likely from leakage, and death occurred twenty-four days after the operation. Only a partial examination could be made, and it was therefore difficult to make out the exact condition of the parts, but apparently a rapid extension of the growth had taken place with which the seat of the anastomosis had become involved. At any rate, the junction had at one part given way and death had resulted from septic peritonitis due to the leakage.

CASE 5. *Malignant growth of the splenic flexure; colectomy; lateral anastomosis of the sigmoid and the transverse colon.*—In this case the patient, a woman, aged fifty-six years, had first noticed a lump on the left side below the ribs two years before her admission to the Newcastle Royal Infirmary. It was small at first, but it had gradually increased in size as time went on. She had severe pain, which was worse at night, and there was gradual emaciation and loss of strength. More than once the bowels, always difficult to move, had been obstructed, accompanied with vomiting. Such an attack came on whilst she was in the hospital. When examined on admission a moveable mass was found in the left hypochrondriac region. An operation was therefore performed on July 27th, 1896. The abdomen was opened in the left linea semilunaris and the mass was found to be a growth of the splenic flexure just at the end of the transverse colon. It was attached at a limited point to the greater curvature of the stomach, though the gastric wall did not itself seem invaded by the disease. As the case seemed favourable for colectomy the bowel was divided at a sufficient distance on either side of the tumour, the open ends being clamped with forceps. The growth could then be well drawn down and its adhesion to the stomach wall was peeled off with the finger-nail. The costo-colic ligament attaching it to the diaphragm was next divided. In separating the peritoneum where this was reflected over the pancreas the substance of the gland was torn and the bleeding from the torn surface gave trouble. When the tumour was detached the open end of the transverse colon was closed by a puckering suture of catgut through all layers. The closed end was then well invaginated and the contiguous peritoneal coat was stitched with a close series of Lembert sutures of catgut. The same method was followed in closing the open end of the descending colon. Finally, the sigmoid and transverse portions were brought in apposition and a wide lateral anastomosis was established between them. The free oozing of blood from the lacerated pancreas, the substance of which was too friable to hold a ligature, necessitated gauze-packing and the employment of a drainage-tube. These were removed on the second day and recovery was uninterrupted till ten days afterwards, when some fæcal discharge escaped from the track of the tube. This discharge became gradually more abundant, though happily without affecting the generally favourable conditions. The discharge soon

Digitized by Google

diminished and when the patient was able to leave the hospital, at the end of August, it had quite ceased and the wound was healed. The patient has been seen lately and continues in all respects well.

The foregoing cases are grouped together as examples of the method of re-establishing continuity of the bowels by lateral anastomosis. Case 1 exhibits the only instance in which any kind of clamp or support was made use of in effecting the junction, and in this case the cohesion effected by the pressure of the plates was not considered sufficient without the additional safeguards of a row of Lembert stitches and a wrap of omentum. When these additional measures are taken the saving of time effected by any form of button or clamp is seriously reduced. As a set off to the saving of time all such mechanical devices have the drawback that they restrict within very moderate limits the communication established between the two segments of intestine. It seems to be a matter of great importance, not only for the immediate relief of the symptoms but still more for the continuance of this relief, that the communicating opening should be exceedingly free; and this can only be secured when the junction is made by sutures alone. The plan followed in the other four cases was the same. The two portions of bowel to be united were placed side by side and where the sides lay in apposition they were joined by a series of Lembert sutures for a length of rather more than 3 in. Then an incision was made into each segment of bowel in that part of the wall opposite the mesenteric attachment and just falling short of the ends of the row of stitches. By an overcast suture through all layers the two openings were next united. This suture began in the margins which were contiguous and as it passed round it was carried through the margin of one opening and then through the corresponding point of the margin of the other, so that when the suture was tightened these were drawn together. In this way one end, then the corresponding outer margins of the two incisions, then the other end back to the point whence the suture started were united, and the openings in the two portions of bowel were converted into one large aperture of communication. To avoid puckering and narrowing of the opening the suture was tied off after each three or four stitches. Lastly, the cincture of Lembert stitches which was begun before opening the intestines was completed. Carried out in this way the suturing can be rapidly done, and as the anastomosis can be made as free as desired there need be no risk of future contraction.

Newcastle-on-Tyne.

LANDRY'S PARALYSIS.

BY ARTHUR S. TAYLOR, M.D. CANTAB., F.R.C.S. ENG.

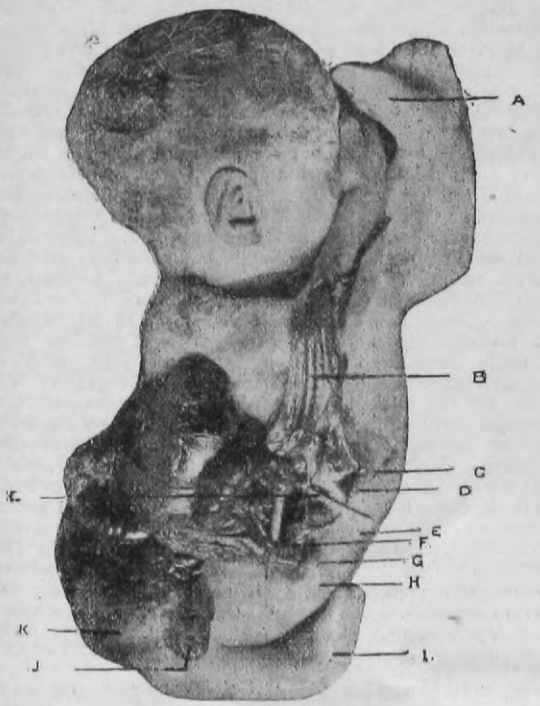
CASES of acute motor paralysis rapidly proving fatal are so rare, especially in this country, that the following remarkable case is of the greatest interest. I have classed it as a case of Landry's paralysis as it appears to me that the symptoms followed more closely the lines of that disease than those of any other lesion of the nervous system with which we are acquainted. The paralysis, however, was not "ascending" as in the majority of cases, and the course of the disease was even more acute than in any I have seen described.

The patient was a man, aged forty-two years, who had been married twelve months. He had always enjoyed exceptionally good health and his life would have been accepted as a first-class one by any life assurance company. About six years ago he had a bad accident, being run over by an omnibus, but from this he completely recovered with the exception that he had a partially stiff left elbow-joint. He had been a good deal worried recently by domestic illness, but the cause had been removed and apparently he was not affected by it in any way. On August 7th, 1898, he went to bed in his usual perfect health. At seven o'clock the next morning he awoke to find his right arm tingling and numb. The left arm was affected similarly but to a less degree. He thought he had been "sleeping on his arm." When given a cup of tea he dropped it and on getting out of bed found that he had not the full power in his legs. There was a good strong grip with either hand. He could walk round the bed but was evidently afraid of falling. His pupils were equal and reacted to light but not perfectly during accommodation. Although he could see and recognise those about him he could only read with great difficulty. The knee-jerk was absent. His mind was perfectly clear and he was able to dictate a good business letter. There was no headache or other pain. Tactile sensation was perfect everywhere. The temperature was normal and the pulse was full and strong but not accelerated. On the afternoon of the same day I found the general loss of power slightly increased, formication of the arms and legs persisted, and the temperature was still normal. He passed a good night, but when I saw him early on the morning of the 9th (the second day of illness) all the symptoms were much intensified. He had now to be assisted to move in the bed. His tongue was slightly furred and the temperature had risen to 100° F. His sight was worse and the pupils no longer reacted to light. There was now also a distinct difficulty in articulation. The brain remained perfectly clear. In the afternoon Dr. James Taylor kindly saw the case with me. By this time it was apparent that the motor paralysis would soon become absolute. The breathing was shallow and bulbar symptoms were much more marked. There was no nystagmus or tremor. The third nerve was involved, as shown by ptosis and by paralysis of accommodation and of all the ocular muscles. The optic discs were normal. There was also paralysis of the soft palate with difficulty in swallowing. The temperature was still 100°. Dr. James Taylor drew attention to the similarity of the condition to that caused by curari poisoning and agreed that the condition was almost hopeless. On the 10th (the third day of illness) the motor paralysis became absolute with the exception that the patient could still move the head slightly from side to side. Any attempt to swallow set up spasms in the facial muscles; the respiration gradually failed and he died at 4.30 P.M. There were no bedsores. The nurse told me that the heart continued to beat long after respiration had ceased, but she did not notice whether abdominal or thoracic respiratory movements ceased first. The rectum and bladder were unaffected throughout and the urine was free from albumin and sugar.

The case was, no doubt, one of acute motor paralysis and it is probable that the whole of the grey matter of the spinal cord was affected. The bulb and the course of the third nerve were also involved. The slight rise of temperature which occurred in this case is, I believe, not usually observed, but the absence of anæsthesia, bedsores, and paralysis of the rectum and bladder sufficiently differentiates the disease from myelitis. The extremely rapid course of the disease and the absence of any symptoms of gross change in the grey matter point to some virulent poisoning of the latter structure and the analogy to curari poisoning lends colour to the theory of some toxic agency. There was little time to adopt any treatment. At the outset iodide of potassium was given, and on the second day $\frac{1}{100}$ grain of strychnine was injected hypodermically every three hours. Possibly this may explain the strong and persistent action of the heart. The patient was fed by nutrient enemata.

Surbiton Hill.

AN EMBRYOLOGICAL CURIOSITY.



BY J. ROSS MACMAHON, M.B., C.M. ABERD.

THE case described in the following paper embodies a number of points of great embryological interest. An alternative heading might have been, "Absence of Abdominal Wall, Bladder, and Anus, with a Semi-cloacal Condition and Bilateral External Genitalia, &c."

The child, an eight-month one, was the sixth offspring of the mother and was not born alive. Throughout her pregnancy the mother exhibited relatively little abdominal protrusion and she averred that she was ignorant of her condition until about one month before her delivery. By abdominal examination the child's parts could easily be felt. Examination *per vaginam* revealed the fact that the sacral region was the presenting part; in other respects matters were consistent with a normal condition. The labour only lasted three or four hours, very little liquor amnii escaped, and the ovum was delivered *in toto*. This circumstance was owing to the fact that the umbilical cord was represented by

Digitized by Google

a condition which obtains about the beginning of the second month of pregnancy. At this period the embryonic somatopleure (the part about to be folded in to form the body wall) is continued on beyond the embryo as the amnion (the extra-embryonic somatopleure) to the already determined placental area of the chorion. This continuation is quite short and the cord-like form between the embryo and the containing membrane is only assumed in later months. It will therefore be evident that consequent on the absence of the long umbilical cord and the presence of its short *anlage* the child and the placenta must of necessity be born together. It may be as well to state here that the child presented a lateral curvature to the right extending from the upper dorsal region of the spine to its lower limit; in addition to this the right lower extremity was doubled so that the sole of the foot apposed the corresponding buttock and the foot was a typical clubfoot. The left lower extremity was placed so that the foot apposed the forehead and was a talipes valgus. The abdominal wall was deficient in a kite-shaped area the tail of which was situated at a point corresponding to the ensiform cartilage, and the sides of which gradually diverged to the widest point rather on the outside of the middle of either Poupart's ligament, from which the dome-shaped head, passing beneath a point corresponding to the absent pubic arch, completed the area. The boundary of this space represented the point where skin formation ceased; beyond this the somatopleure, or body wall, passed on as in an early stage to become amnion. Through this gap the abdominal viscera protruded, the right kidney being rendered particularly prominent by a well-marked hydronephrosis as large as a duck's egg. The bladder was deficient, the left kidney occupying the site. It was indicated, however, by a very curious state of things, which is all the more interesting when compared with extroversion of the bladder of congenital origin and the condition of the genitals usually concomitant with that event. Bordering the middle line on

A, Talipes valgus. B, Umbilical vessels. C, Scrotum. D, Penis. E, Anal dimple. F, Ureter of left kidney. G, Penis. H, Scrotum. I, Pes varus. J, Right kidney. K, Hydronephrosis. L, End of gut with quill passed through.

either side an ill-defined leaf-shaped space was visible on the lower end of the body wall, and here, in contrast to the surrounding somatopleure, two layers could be felt and rolled over each other. The two areas were quite independent and their walls could be separated and dissected up to the middle line, where they fused. This condition is really suggestive of a precursory duplex bladder and would seem to imply a bifid allantois. Into each area a ureter could be traced, so far as could be made out, ending blindly on the right side (that of the hydronephrosis), but having a minute opening on the left side. The lower margin of the spaces formed most of the dome of the kite-shaped deficiency of the abdominal wall; below this skin formation commenced and passed along to the perineum. Situated at this point on either side and about an inch apart was a well-formed though diminutive penis. Each penis presented a glans, a prepuce and a closed meatus urinarius, and below them the skin was sacculate and thrown into loose folds so as to form a scrotum. The testes had not descended and were lying high up, where they were formed from the genital ridge. The duplex quasi-bladder corresponded well with the formation of two penes, but there was no communication between the penes and the bladders. On the under or dorsal side of each penis a distinct but comparatively faint raphé was observable, indicating the presence of two uro-genital sinuses at an earlier period.

Before passing to perhaps the most interesting abnormality which was manifested in this case it may be opportune to observe that in normal pregnancies the cloaca in the human embryo exists up to the fourteenth week. Into it open the two Wolffian ducts, the two fused Müllerian ducts, the allantois, and the intestine. A vertical division of the cloaca from side to side, growing up from below in the form of an epithelial plate, divides it into an anterior or uro-genital opening and a posterior or anal opening. This involves the complete separation of the uro-genital system from the intestinal canal. The Wolffian ducts form the kidneys and ureters in both sexes, and the spermiduct, seminal vesicles, &c., in the male, and the connexion with the gut then vanishes. The Müllerian ducts fuse before entering the cloaca per the neck of the allantois. In the female they form the uterus, the vagina, the Fallopian tubes, &c.; but in the male a remnant is retained in the uterus masculinus. In the present case the anus was represented by a slight dimpling at the normal site, but no perforation had occurred and the gut ended in the middle line between the two bladder areas. The termination was abrupt and was situated just in front of the skin of the perineum and it was quite patent. About 1 in. above the end of the gut, and communicating with it posteriorly, lay numerous coils of tube of varying circumference. These occupied a site behind the gut, and on a close inspection it could be seen that the mass really consisted of three distinct and blind tubes all conducting to the rectum. On slitting the rectum with scissors the three openings could be seen and a quill could be passed into each. The tubes were arranged one on each side of a larger and central one. The two lateral tubes were of equal lumen and length and were placed symmetrically. The central one was much longer and of much greater circumference and it gradually tapered off at its blind end. A semi-cloacal condition of things was thus revealed. The central blind duct was doubtless the fused Müllerian ducts (the uterus, Fallopian tube, &c., in the female) which had remained instead of undergoing resorption and disappearing. The two lateral tubes were the remnants of the two Wolffian ducts which had also failed to disappear. Some distance up the large intestine was a narrow strip of cicatricial-like tissue 2 in. long; it was flat and smooth and felt like a piece of parchment let into the long axis of the gut. This doubtless was the site of the closure of the yelk sac. Around this the bowel was gathered up in pleats and puckers which radiated outwards. Strangely enough, there was absolutely no sign of an appendix vermiformis, but some inches above the closure of the yelk sac, and corresponding exactly to the site at which the appendix should come off, was an exact facsimile, in miniature, of the condition described at the closure of the yelk sac. The parchment-like longitudinal plateau, the puckering of the gut, &c., were all represented.

In reviewing the case I would suggest that the cause of the limb and spinal deformity was the dearth of liquor amnii. Pressure would be a consequence of this deficiency, and the position and deformities of the child were consistent with this theory. The idea might be carried further, and it would be reasonable to suppose that the scantiness of the liquor amnii, combined with the resulting position of the legs of the fœtus, exerted a combative influence against the normal evolution of the other parts.

TRAUMATIC SEPARATION OF THE LOWER EPIPHYSIS OF THE HUMERUS WITH DISPLACEMENT FORWARDS.

BY W. McADAM ECCLES, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, WEST LONDON HOSPITAL, CITY OF LONDON TRUSS SOCIETY, DEMONSTRATOR OF OPERATIVE SURGERY AT ST. BARTHOLOMEW'S HOSPITAL, ETC.

THE rarity of displacement *forwards* after separation of the lower epiphysis of the humerus induces me to put on record the following case.

A boy, aged ten years, living in the country fell, as I understand, from a see-saw, or swing, alighting on his right hand. Shortly afterwards the elbow was painful, but as there was no idea of any serious injury having occurred medical advice was not sought until some time had elapsed and no splint was applied. At the end of three weeks, as the elbow remained stiff and slightly swollen, the patient was brought up to town. The right forearm was in a position of flexion, forming an angle of 145° with the arm, and the boy was unable to extend it voluntarily any further. Full flexion, however, could be satisfactorily accomplished and practically without discomfort. The biceps cubiti was kept contracted. The forearm, moreover, was somewhat pronated and it was impossible for the patient by his own effort to completely supinate without pain. Examination under ether showed flexion to be free, but extension impeded though it could be forcibly accomplished. Creaking about the joint was noticed, but all the usual movements were nearly normal in their range. When I saw him first in consultation with Dr. John Shaw-Mackenzie between four and five weeks after the original injury, it was observable that there was no evidence of inflammation about the joint. A distinct dimple could be seen about the tip of the olecranon process, which was not apparent on the sound side. The three bony prominences bore their normal relationship to one another, but appeared to be on a plane anterior to the shaft of the humerus when compared with the left side. Measurement of the arm gave a like length on the two sides, but the distance from the projecting part of the humerus on the outer side to the radial styloid process showed some increase in the length of the forearm. Forcible movement without an anæsthetic proved that full extension of the elbow joint was impossible, though flexion could be readily brought about. The other points were much the same as those alluded to above. Seeing the unusual nature and uncertainty of the lesion my friend, Dr. F. H. Low, very kindly and successfully skiagraphed both the normal and abnormal elbow-joints. Each limb was placed with its inner surface upon the sensitive plate, with the elbow flexed at a right angle. The prints from the negatives showed very clearly the dimple mentioned before in the curve of the line of the soft parts. It showed, further, that the breadth of the limb at the region of the elbow was distinctly increased, and this without there being any local swelling or œdema. The ossific centres of the lower epiphysis were displaced distinctly forwards, well shown by their relationship to the shaft of the humerus.

I have been unable to find more than a few references to what I believe the case under review to be—namely, a traumatic separation of the lower epiphysis of the humerus with displacement forwards. Hamilton[1] does not mention it and Pick[2] makes no allusion to it, nor does R. W. Smith[3] in his paper on the subject. All these and other authorities give a full account of the much more common *backward* displacement. An excellent skiagram of this latter deformity is given by Roswell Park.[4] J. Hutchinson, jun., says[5]: "Very occasionally the epiphysis is driven forwards instead of backwards," and in one case under his care the forward displacement was well marked. I believe the prognosis as to the subsequent growth and usefulness of the limb is good in the majority of these cases, provided that passive movement, together with massage, is early resorted to. In this particular case the patient has now a useful limb, with but little deformity, although it has taken many months to bring this result about

CHLORODYNE POISONING

BY JAMES GILROY, M.B., C.M. GLASG.

ON Jan. 15th, 1895, at 12.30 A.M., I was called to see a man, aged seventy years. Having to travel two miles I did not see him till 1 A.M. I found him unconscious with stertorous breathing and the pupils unequal, the left being contracted to a pin's point and the right moderately dilated. The surface of the body was fairly warm, there was a considerable amount of perspiration over the trunk, and the pulse was full and regular, being about 70 per minute. The history I got was that about 8.30 P.M. on the 14th he had retired to bed as was his wont and that later, about 11 P.M., some of his family fancied they heard unusually heavy breathing and entered his room, having to force the door, and found the patient on the floor; lying in close proximity was a bottle of cough mixture, an eight-ounce bottle, which was three-quarters empty, leaving scarcely two ounces in the bottle. The mixture smelt strongly of chlorodyne and was a patent medicine labelled "Joe Todd and Co.," with a graduated dose scale given on the label up to one tablespoonful and "not intended for infants" printed thereon, together with an intimation on the reverse side that "owing to containing morphine and other valuable drugs" the requirements of the law required it to be labelled "poison." I was told that before I had arrived the patient had vomited slightly, his son having administered mustard and water and put him to bed. Not having had any intimation of the nature of the case I had nothing with me, but despatched a messenger for the stomach tube and some emetics and meanwhile I proceeded to try to rouse the patient, which was apparently indicated. This was done by pinching him, signs of pain being evinced, and by getting him out of bed and walking him about as best we could for upwards of an hour. He exhibited signs of knowing what was being done, but his condition was, to say the least, alarming. On arrival of the tube I washed out the stomach freely with hot water and followed by introducing some infusion of green tea and later some Liebig's extract in hot water. About 5 A.M. I left him, after having expended some considerable effort, and finding that on speaking loudly to him he evinced signs of consciousness. I called again at 4 P.M. I found him still sleeping soundly, the pupils being in the same condition as before; there was no change. I introduced into the stomach two-thirds of a quart of warmed milk with a little lime-water, and left him, to return again at midnight to find the same state of affairs, when I again introduced about one pint of milk with the stomach tube. I continued to attend the patient twice daily all the week and the treatment was as stated all through until the afternoon of the 18th, when he awoke and sat up to assist me with the tube, which he appeared quite to understand was being used for his benefit, but he did not speak, though when he was spoken to his lips moved as if he were attempting to answer. On the 16th I noticed the odour of opium very perceptibly in his breath, but on no other day could I detect it except more faintly on the 17th. On the 19th, on my visiting him in the afternoon, he spoke to me quite plainly, asking if he had been asleep over twenty minutes. All through there was no involuntary discharge of urine. It was passed naturally and was loaded with urates, and only on one day—viz., the 17th—was it retained over twenty-four hours.

The patient told me that the dilated eye had been one for which he had had special advice and treatment, but whether that had anything to do with the inequality of the pupils is another question; but I noted that the condition was still present on the 23rd—that is to say, although the firm contraction had yielded in one eye the other pupil was larger. He was then taking his food well and was very hungry. On the 19th the history I got was that his demands for food were incessant, whilst on the 23rd he had practically recovered. The mixture came into his possession on the evening of the 12th and he simply drank it *ad libitum* at intervals, and admitted taking a drink of it from the bottle,

Digitized by Google

using no measure, on his entering his room on the evening of the 14th, but he remembered nothing else.

Waterbeck, Dumfriesshire.

RUPTURE OF THE LEFT CORONARY ARTERY; HÆMOPERICARDIUM; FAILURE OF PULSE IN THE RIGHT CAROTID AND RADIAL ARTERIES.

BY LAURENCE HUMPHRY, M.D. CANTAB.,
ASSISTANT PHYSICIAN, ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THE following case is worthy of record, partly on account of its clinical interest and partly because it reveals a somewhat rare pathological condition.

The patient was a woman, aged fifty-eight years, and unmarried. She had always enjoyed good health except that about thirty years ago she had suffered temporarily from albuminuria. Up to the time of her death she was active and free from breathlessness and pain and a few months previously she had taken long walks on the mountains without undue fatigue. On Nov. 15th, 1896, while she was at breakfast she complained of a sense of faintness and dizziness and soon afterwards she was violently sick. When she was seen at 9.30 A.M. she was lying on the floor looking pale and anxious. She complained of pain in the stomach and a feeling of numbness on the right side. The right radial pulse was imperceptible, the left was 100 and was feeble and irregular in force. The præcordial dulness was not increased and the apex beat was not felt; the heart-sounds were feeble at the apex, and a roughness was noticed with both sounds at the base. The extremities were cold and clammy. Hot bottles and stimulants were ordered and a mustard plaster was placed over the præcordia. Two hours later she was very restless and was unable to express herself coherently. Her face was pale and cyanosed and the right jugular vein appeared full and prominent. The bowels had acted copiously and the sickness was decreasing; she could move all her limbs and only complained of pain at the pit of the stomach. During the afternoon she was evidently getting weaker and less conscious. The right pulse was still absent but on further examination the radial vessel on that side could be distinguished and rolled under the finger, though it was not distinctly hard. The right brachial artery could also be felt but pulseless, and no beat could be distinguished in the right carotid artery. The left pulse was quite distinct, but feeble, irregular, and intermitting slightly with inspiration. At this time it was noticed that on turning the patient over on to the left side to give a nutrient injection the right pulse could be distinctly felt and continued as long as she remained in that position, but disappeared again immediately on turning on to her back. A rapid auscultation of the back on the right side indicated some tubular breathing at the angle of the right scapula but owing to the patient's condition no further examination could be made. In the evening there were several loose actions of the bowels containing small quantities of red blood. The patient never rallied, but became weaker and died at 2 A.M on Nov. 16th, 17 hours after the first onset of the attack.

Necropsy.—At the post-mortem examination the large veins of the neck were found distended and prominent. The pericardium bulged slightly but was covered by the left lung to the normal extent. The pericardial cavity contained about from 5 oz. to 6 oz. of blood and clot. The heart appeared of normal size and weight but the walls were soft and flabby. There was no evidence of any valvular disease. On the surface of the heart near the aorta was a small opening of the size of the head of a large pin and here there was much extravasation of blood into the muscular tissue and fat and upwards into the fold of pericardium ensheathing the first part of the aorta. The result of this was the production of a swelling which reached so high as to cause pressure on the innominate artery. There were a few patches of atheroma in the aorta and both coronary arteries were throughout the seat of extensive atheromatous disease. They were both dilated and the left coronary artery was ruptured about a quarter of an inch from its exit from the aorta, the rupture corresponding in situation to the small orifice above described. There was no sign of a small aneurysm of the coronary vessel and the sinuses of Valsalva were normal. The muscular substance of the heart was in an advanced state of fatty degeneration.

Remarks.—Rupture of a coronary artery appears to be a rare incident and there are but few recorded cases. In THE LANCET of June 4th, 1887, Dr. J. W. Batterham records a case in which there was a rupture of the coronary artery near the apex of the heart causing hæmopericardium, and in *The Medical Times and Gazette* of March, 1862, Mr. Osborne describes a case in which the coronary artery was ruptured near its origin from the aorta. The coronary artery is sometimes the seat of a small aneurysm which may rupture, and in the Transactions of the Pathological Society of London for 1871 Dr. Crisp has collected 11 cases, all occurring in males, and in 7 of which rupture took place into the pericardium. The failure of the right pulse beat in this case is very interesting and in the absence of any other explanation must, I think, be attributed to the pressure of the extravasated blood upon the innominate artery. The swelling produced in this situation was very obvious after death and was probably greater during life as the blood continued to escape into it. While the patient was lying on her back with the head low the pressure was sufficient to obstruct the pulse in the innominate artery, but when she was turned on to the left side the blood in the pericardium flowed towards the apex and relieved the pressure sufficiently for the pulse to return. The tubular breathing heard at the right base behind may have been due to the pericardial effusion, but whether this sign was present on the left side also I am unable to say. Other noteworthy features in the case are the absence of angina and the fact that the patient had been able to take very active exercise in spite of the advanced fatty degeneration of the heart muscle and the extensive atheroma of the coronary vessels.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF BELLADONNA POISONING.

BY R. A. MORRIS, M.B., B.S. DURH.,
LATE RESIDENT ASSISTANT HOUSE SURGEON, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

ON Feb. 24th, 1897, I was called to see a man, aged forty years, a patient of mine, who was suffering from pleurisy with effusion on the right side and phlebitis of the right femoral. For the latter he was using a paint composed of extract of belladonna ½ oz. with glycerine to 1 oz. At 7.15 A.M. his daughter, aged twelve years, went to give him a dose of medicine and in mistake gave him a tablespoonful of the preparation just mentioned, so that he got 2 drachms of extract of belladonna. When I saw him at 10.30 A.M. he was comatose, his breathing was very shallow, his pulse was almost imperceptible, his skin was dry and the pupils were widely dilated. I immediately gave him a hypodermic injection of ¼ gr. of pilocarpine hydrochlorate and washed out his stomach. I may state that before I saw him his wife had administered some mustard and water, which caused him to vomit about a wineglassful of fluid, but there was little or none of the belladonna in the vomit which was kept for my inspection. The fluid which came away when I introduced the stomach tube contained a considerable amount of the poison. Subsequently to washing out the stomach I introduced a quart of strong coffee, a little of which he vomited. I gave him another hypodermic injection of ¼ gr. of pilocarpine hydrochlorate. His breathing by this time was much deeper and his pulse was much stronger, 120 to the minute, and he now tried to push away those near him. His wife said that

Digitized by Google

previously to his becoming unconscious he complained of soreness and dryness of the throat; he occasionally smiled and muttered, but never laughed outright or talked loudly. I left him at 12.15 P.M. He was muttering a little but both pulse and respiration were strong.

On seeing him again at 2.30 P.M. his temperature was 102·7° F., but it must be remembered that his temperature was previously 100° from the pleurisy and phlebitis. He was now conscious of what was said to him, putting out his tongue when I asked him to do so. He would not attempt to swallow anything. The pupils were still very widely dilated and did not react to light. I again administered ⅓ gr. of pilocarpine, thus making in all ⅔ gr. There was no scarlatiniform rash to be seen and no paralysis of the sphincters. He frequently retched, but he never vomited subsequently to the vomiting which followed the dose of mustard and water. On seeing him again at 7.30 P.M. his pupils were still much dilated and did not react to light. On attempting to take a little coffee he felt very sick but did not vomit. His temperature was now 102·2°. He recognised me but did not remember what had taken place beforehand. On Feb. 25th his temperature was 100°, his pulse was 108, and he was sweating profusely, as he had done all night. He had had some disturbed sleep. He fancied he saw black things moving about during the night, and also fancied that the pictures in the room were all kinds of strange animals, although he knew they were the pictures. On closing his eyes tightly there was an awful blackness with white stars here and there. The pupils were still dilated but reacted slightly. On examining his chest I found that it was markedly improved, the effusion having nearly all gone. He described himself as being sore all over but with no definite pain. On Feb. 27th the pupils were normal, the temperature was 99·4°, and the pulse was 92.

Bedlington, Northumberland.

PIN IN THE RECTUM FOR THIRTY YEARS.

BY W. DUTTON AKERS, M.R.C.S. ENG., L.R.C.P. LOND.

A MAN, aged fifty-eight years, a linendraper, consulted me with a view to obtaining relief from the following symptoms. He had pain in the rectal region of a pricking character on sitting down, constant desire to defecate, great pain on doing so, and the motions were small, pipe-like and streaked with blood. These symptoms had been present with more or less intensity for a period of thirty years; he had frequently sought medical aid, and the treatment generally took the form of morphia suppositories or other local applications. Examination revealed the presence of external hæmorrhoids, and digitally considerable induration and inflammation of the mucous membrane covering the internal sphincter was detected. Above and at the right side of the internal sphincter the head and about half an inch of the body of a pin were to be felt, the head projecting upwards and somewhat across the lumen of the intestine. With the aid of a pair of long dressing forceps introduced by the side of the examining finger the pin was pushed up into the rectum, rotated, and then extracted head foremost. Thanks to the pluck exhibited by the patient I was enabled to carry out this painful manipulation without an anæsthetic. The removal of the *fons et origo mali* was followed by a rapid subsidence of the symptoms which had prevailed for so many years. This case illustrates the great importance of making a careful examination of the rectum in such cases. I suspected carcinoma and found an easily removeable pin. The patient was unable to account for the pin, but his occupation is a sufficient explanation.

Bath.

STRANGULATED HERNIA IN AN INFANT.

BY J. E. BRISCOE, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a small, healthy child, twenty-one days old, who had been quite well up to the evening of the day before my visit (Sept. 8th, 1896), became cross from no obvious cause and a dose of castor-oil was given. Later in the evening a small motion was passed, but the child continued to be extremely fretful and was at 9 A.M. next day evidently ill, the face appearing pinched. Vomiting had occurred once and no motion or flatus had passed since the day before. The scrotum was slightly œdematous and red on the right side and distended by a very tense pear-shared swelling. The swelling seemed to end completely at the external inguinal ring and no alteration was discovered in it when the child cried. The physical signs were those of inflamed hydrocele, but the symptoms pointed to hernia, and a hot bath having been given an attempt at reduction was made, but with no success. Under chloroform—administered by Dr. David Watson—an incision was made into the sac. From one to two drachms of dark serous fluid escaped and a coil of bowel, thickened and distended, dark-purple in colour but still glossy, was exposed. The length of the coil was from 3 in. to 4 in. The walls of the sac, the epididymis, and the cord behind were very deeply congested. With the child inverted a second attempt at reduction was made. This failing the canal was dissected up and the internal ring was laid bare. Throughout the whole length of the canal the bowel was tightly invested by the thickened peritoneal tube and at the internal ring the constriction was very marked. The point of a Lister's sinus forceps was, however, passed through the ring and was then brought out above the upper margin, and the portion thus separated was divided on the forceps as on a director. A further quantity of dark fluid escaped from the abdominal cavity when this was done. The bowel was then easily reduced on inverting the child. The ring was closed by two catgut sutures and the edges of the incision were brought together loosely by two sutures of silkworm gut. Healing was rapid and uninterrupted. The bowels acted regularly from the first night.

I think the following are points of interest in the case: (1) the youth of the child; (2) the apparent abrupt termination of the sac at the ring, leading to a very close resemblance to hydrocele; and (3), the tight tube of peritoneum which surrounded the bowel. Nothing larger than the point of a probe could pass along this and I was in consequence obliged to make an open dissection of the canal. How the bowel entered this tube is a mystery.

The child still wears a woollen truss of the kind described in Pye's "Surgical Handicraft" which has been worn since a fortnight after the operation, and in this case as in other cases of congenital hernia it answers admirably as a support to the ring.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prœmium.

ROYAL FREE HOSPITAL.

A CASE OF COMPOUND FRACTURE OF THE PATELLA DUE TO A KICK FROM A HORSE; RECOVERY WITH A MOVEABLE JOINT.

(Under the care of Mr. W. H. BATTLE.)

THE value of modern surgery is in few conditions more strikingly shown than in wounds of joints. In pre-antiseptic days an extensive wound of any large joint was certain to be followed by prolonged suppuration, in only too many cases terminating in septicæmia or pyæmia; and so fully were these dangers recognised that a primary amputation was often advocated. The importance of a wound of a knee-joint was greatly aggravated by fracture of the patella, for even if the patient were fortunate enough to survive the lengthy suppuration and its concomitant septic dangers he was left with a limb which was absolutely useless for walking. The contrast between these severe symptoms and results and the effects of modern treatment are strikingly shown in the following account of a compound fracture of the patella. Recovery was rapid and practically uneventful, for the slight rise of the temperature which occurred on one occasion immediately disappeared after the administration of an enema.

A cabman, aged fifty-three years, was admitted into the Royal Free Hospital on April 20th, 1898, for injuries to his

Digitized by Google

knees. Shortly before his admission to the hospital he was, whilst sitting on the driving seat of his cab, kicked on both knees by the horse, a vicious animal, the splash-board being destroyed. On the left knee there was only a small and comparatively unimportant wound extending down to the patella, but on the right knee there was a transverse lacerated wound extending almost the whole width of the limb. Through this opening the interior of the knee-joint could be seen, and it was at once evident that the right patella had been broken transversely into two large pieces, though several smaller fragments could be felt. The two large pieces formed about five-sixths of the patella. The wounds were temporarily dressed with an antiseptic application and a back splint was applied to the right leg. On the evening of the day of admission, about five hours after the accident happened, the patient was anæsthetised and Mr. Battle, who had been sent for, proceeded to wire the bone. An incision three inches long was made directly upwards from the middle of the horizontal wound on the right knee, the flaps were reflected on each side of this incision, and the knee-joint was completely exposed. The joint cavity, the bony fragments, and the surrounding parts were then thoroughly washed in a solution of perchloride of mercury (1 in 2000). Two or three small fragments required removal. Then the two larger pieces of bone were joined together with silver wire and the ends of the wire, after having been twisted, were hammered on to one of the fragments. The aponeurosis over the patella was united by silk sutures and the edges of the skin wound, having been carefully pared, were drawn together with interrupted sutures. A drainage-tube was inserted through a separate incision in the outer side of the joint. A dressing of double cyanide gauze and absorbent wool was applied and the limb was enclosed in a plaster-of-Paris splint. The wound on the left knee was sutured and dressed in a similar manner. On April 22nd the right knee was dressed and the drainage-tube was removed. On the 24th the temperature rose to 100° F. but fell to normal on the bowels being opened by an enema. On May 3rd the skin stitches were removed and the plaster-of-Paris splint was exchanged for a wooden back splint. On the 12th the patient was allowed to sit up and on the 19th the splint was removed, a small dressing only being applied. On the 24th he was discharged from the hospital; he had firm union of the patella and was able to walk. Further improvement has resulted.

Remarks by Mr. BATTLE.—The patient was not regarded as a favourable subject for operation, his occupation and appearance suggesting that he was not a teetotaler. He was a stout, heavy man, with dilated cheek capillaries. Subsequent examination, however, did not show any visceral disease, although his arteries were hard and tortuous. In a simple fracture of the patella there are many conditions to be taken into account by the surgeon before he can decide whether it is best to wire the patella or not, whereas in a case of compound fracture he has no option; the fragments if they are of sufficient size must be wired if the joint is to be rendered useful in the future. In addition it is imperative that the wound should be rendered thoroughly aseptic and here the treatment which the case first receives is of the greatest importance. If when the patient is first seen the applications to the wound are thoroughly applied a successful result may be hoped for, but if not a suppuration in the joint at the least is to be feared. When wiring is performed for simple fracture the surgeon can prepare the patient and make the outside of the joint aseptic, he can also choose his own time for the operation; these conditions do not apply in compound fracture. Some months ago I showed at the Medical Society of London a case of compound fracture of the patella in a young man caused by a fall of several feet from a ladder with his bent knee striking on the edge of a barrel. He was under my care at St. Thomas's Hospital and a result in every way satisfactory was secured without suppuration after wiring. In both instances much credit is due to the house surgeons for their earlier treatment and prompt recognition of the injury, as well as for their great care in the after treatment.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

THREE CASES OF FÆCAL FISTULA TREATED BY OPERATION.

(Under the care of Mr. RUTHERFORD MORISON.)

ALL the three cases recorded below are of interest. In the first a correct diagnosis was made and the extent of the tuberculous disease of the bowel necessitated a wide operation, fully justified by the complete removal of all the diseased intestine; it was not found necessary or even desirable to employ any mechanical contrivance for effecting the intestinal anastomosis. In the second case a subperitoneal abscess had burrowed widely in the anterior abdominal wall and had perforated the transverse colon as well as the skin. Although the suppuration had commenced in the right side it was quite unconnected with the vermiform appendix, which was healthy. The third case illustrates a sequela of lateral lithotomy which is much less frequently met with now than formerly, chiefly because the operation itself is not so often performed. For the notes of the cases we are indebted to Dr. Grant Arnott, house surgeon.

CASE 1.—A girl, sixteen years of age, was admitted to the Royal Infirmary, Newcastle-on-Tyne, on Dec. 1st, 1897. The patient was very small and ill-developed and had always been delicate. Fourteen months previously to her admission a painful swelling appeared in the right side of her abdomen. A month later this lump burst and discharged pus and fæces. Three openings formed which had discharged ever since. At first most of the fæces passed through these openings and very little *per anum*, but for some months the greater part of the motions had been passed naturally. On admission to the infirmary her general condition was very bad and she suffered from constant discomfort. In consequence of the leakage of fluid fæces she had a painful dermatitis of the skin at the lower part of her abdomen. In the right iliac region, surrounded by cicatricial tissue, were three fistulous openings discharging pus and fæces. Underneath the fistulæ there was a hard mass of the size of half an orange, apparently in the head of the cæcum. The constant discharge of fluid fæces led to a diagnosis of fistula in the small intestine. The hard mass and the general appearance of the patient, with the history suggested tuberculous infiltration and ulceration of the cæcum. The diagnosis of tuberculous ulceration of the cæcum, ileum, and ileo-cæcal valve was made. The condition of the patient was intolerable to herself and others and careful treatment by competent surgeons had failed to relieve her. Operative treatment was therefore imperative. Accordingly, on Dec. 9th an elliptical incision was made round the fistulæ and the infiltrated skin. The two ends of the ellipse were then prolonged anteriorly to the middle line and posteriorly to the back of the ilio-costal space. The abdominal cavity was opened in this line and carefully packed off with sterile gauze. The cæcum was firmly adherent to the abdominal wall and also a loop of ileum 1 ft. from the ileo-cæcal valve. Both portions of intestine were thick, firm, and infiltrated with tubercle. The ileum was clamped between two pairs of forceps and divided on the proximal side of the fistula, and the diseased portion, together with about 18 in. of healthy bowel between it and the diseased cæcum, was separated from its mesenteric attachment up to the cæcum. The ascending colon was then divided between two pairs of forceps beyond the diseased cæcum, which was cut away still attached to the ileum. Along with the cæcum a large tuberculous gland was taken out of the meso-cæcum. This part of the operation was difficult because of extensive and firm adhesions. The forceps holding the cut end of the ileum and the colon were next drawn forward and a continuous catgut suture which was run through all the coats closed the cut ends of the intestine before the forceps were removed. When this had been done the portion of the intestine gripped by the forceps was doubled in and retained by a few interrupted Lembert's sutures. A lateral anastomosis was then made between the ileum and the transverse colon by an inner continuous suture of catgut through all the coats and by an interrupted ring of silk Lembert's sutures. The wound in the abdominal wall was closed by strong silk sutures through the different layers. There was considerable tension on these sutures owing to a portion of the abdominal wall, which was infiltrated and adherent to the intestine, having been excised. The excised intestine showed a healed tuberculous ulcer of the ileum causing stricture and an infiltrated, contracted, and ulcerated cæcum. Both the ileum and the cæcum had fistulous openings in them. Immediately after the operation the patient was much collapsed, but she rallied after having been transfused with 40 oz. of normal saline solution. No fæces have escaped from the wound since the operation, her bowels have been moved without difficulty, her appetite has been good, and her general condition is satisfactory.

CASE 2.—A girl, aged nine years and six months, was admitted to the infirmary on Feb. 12th, 1898. She had had attacks of pain in the abdomen, accompanied by vomiting,

Digitized by Google

for six years. These attacks came on periodically and were attended by constipation. In the intervals she frequently had diarrhœa. About six months before admission an abscess formed at the umbilicus and burst. Fæces and pus were discharged from it and had continued to do so ever since. On admission a small opening was found at the umbilicus discharging pus which was neutral in reaction and had no fæcal odour. On pressing on the abdomen fæcal matter was seen to come through the opening. A hard tender mass of the size of a hen's egg was felt in the right iliac fossa; otherwise nothing abnormal was discovered. The patient was well nourished and the pulse and temperature were normal. On Feb. 17th an elliptical incision was made round the umbilicus, including the fistulous opening. The umbilicus and the outer opening of the fistula were excised. The incision was then prolonged downwards to the pubes in the middle line, but no entrance could be effected on account of adhesions. The incision was next extended upwards and the abdominal cavity was entered above the umbilicus. A sinus was then found to extend in the subperitoneal tissue from the neighbourhood of the umbilicus down to the right iliac fossa and into a coil of thickened ileum adherent there. This formed the mass discovered before the operation. The ileum was separated and the hole in it was closed by a continuous catgut suture through all the coats, and outside of this interrupted Lembert's sutures, transversely to the axis of the bowel. The sinus was then dissected out from the parietes. As this was being done the track was found to branch upwards and to extend to an opening in the hepatic flexure of the colon. The colon was dissected from the parietes and the opening in it was closed in the same manner as that in the ileum. To remove the sinus in the parietes it was necessary to extend a second incision from the middle line to the right iliac fossa. The appendix was found to be normal. The abdomen was completely closed with silk sutures. The patient never appeared to be ill after the operation and made a good recovery. The only drawbacks experienced were some superficial gaping and suppuration of the transverse portion of the abdominal wound, which granulated up. There was no fæcal discharge from the wound.

CASE 3.—A man, aged twenty-seven years, had a lateral lithotomy performed on him seventeen years before his admission to the infirmary, since when he had suffered from constant discomfort and annoyance owing to the passage of fæces and flatus by the urethra. He had enjoyed good health till three and a half years before admission, when he became ill and an abscess formed in the right loin and was opened. Since then his general condition had improved. He was in good health with the exception of the urinary organs. The urine, which on examination was found to be acid and of specific gravity 1017, smelt rather fæcal and contained pus, bacteria, and blood. The quantity passed for the twenty-four hours preceding the operation was 16 oz. On examination under an anæsthetic with a catheter in the bladder and a finger in the rectum a round hole of about the size of a split pea could be felt in the anterior wall of the rectum, slightly to the left of the middle line, about 1½ in. above the anus. A probe passed through the opening touched the catheter in the prostatic portion of the urethra. A scar was present in the perineum in the position of a lateral lithotomy wound. An operation was performed on Feb. 7th, 1898. The patient was placed in the lithotomy position and a semilunar incision was made through the skin of the perineum from one tuberosity of the ischium to the other. The skin flap was dissected downwards and a transverse incision was made across the perineum and the rectum was separated from the urethra, previously catheterised. The openings in the rectum and in the urethra were then both plainly seen. The hole in the urethra was closed vertically by fine catgut sutures over a No. 18 catheter, avoiding the mucous membrane. The opening into the rectum was treated in a similar manner. Buried sutures of catgut were then deeply introduced and tightened, making the transverse incision antero-posterior, much the same as is done in Mr. Lawson Tait's operation for ruptured perineum. The sinus in the lumbar region was explored and scraped. (So far as could be ascertained no urine had ever come through this.) The after progress of the case was good. No urine escaped from the wound after the operation and from the second day the amount of urine passed rose to the normal. The perineal wound healed by first intention. The patient was seen again in June of this year, when the sinus in the back was found to be reduced to very small dimensions. There was still a trace of pus in the urine.

Remarks by Mr. MORISON.—Case 3 is interesting in connexion with the recent suggestions concerning transplantation of the ureter into the intestine. The patient had no trouble except for the disagreeable experience of passing fæces and flatus *per urethram* for thirteen and a half years. It was evident that most of the urine which passed into the bowel was absorbed. The quantity of urine passed before the operation compared with that passed after and the fact that his bowels were regular and the motions of normal consistence make this certain. Although no urine escaped through the sinus in the back it appears to be fairly clear that the abscess in the loin was connected with the kidney. This seems to be the great risk of such operations and the danger evidently cannot be considered to be removed for some time after an apparently successful operative result.

Reviews and Notices of Books.

On Cardiac Failure and its Treatment, with especial reference to the Use of Baths and Exercises. By ALEXANDER MORISON, M.D., F.R.C.P. Edin. London: The Rebman Publishing Company, Limited. 1897. Pp. 256.

THIS is essentially a "Nauheim" book in its latter portion, with the usual presentation of sphygmograms and areas of cardiac dulness in illustrative cases. But the author has attempted a good deal more than this, and the earlier portion of the work is a disquisition on cardiac failure from a general standpoint. It commences, somewhat unnecessarily, with the elementary anatomical facts about the position and relations of the heart and the methods of palpation, auscultation, and percussion, which, as the book is not for beginners, might judiciously have been omitted. They are, however, very well put and are mingled with a number of clinical observations of no small value. The writer follows the late Sir Richard Quain in his views on the causation of the first heart-sound, and his remarks on "cantering" action and quadruplication of the heart-sounds are worthy of attention. The sections on the extra-cardiac signs of cardiac failure and on the signs in the nervous system are also good. The pathology of cardiac failure receives somewhat inadequate consideration in the second division of the book. It is perhaps too much to expect that such work as that of Starling, set forth in his Arris and Gale Lectures (1897), should be incorporated in a book published in the same year, but that is the kind of solid substratum which is wanting in Dr. Morison's volume. The third division of the book is devoted to the general treatment of cardiac failure, and here we find a fair *résumé* of current doctrine on the subject, though there is nothing of any novelty. The latter half of the book is devoted to baths and gymnastics, chiefly to the Nauheim treatment. The author has, of course, visited Nauheim and is very fair and dispassionate and states facts as he has found them from his own observations. The treatment is, as is now well recognised, an excellent one in certain selected cases and Dr. Morison does not err in indiscriminately recommending it. The effect of mechanical exercises as devised by Zander, Oertel, and Schott is discussed at considerable length. There is an appendix by Medizinalrat Dr. Groedel of Bad Nauheim in which the ground is recapitulated. The book contains a good deal of useful clinical observation.

Manual of Chemical Analysis, Qualitative and Quantitative. By G. S. NEWTH, F.I.C., F.C.S. London: Longmans, Green and Co. 1898. Price 6*s.* 6*d.*

MR. NEWTH opens his preface with a very sensible diatribe against the somewhat prevalent idea that a specific analysis may be performed satisfactorily without learning more than a minimum amount of chemistry. Thus as a teacher he was once introduced to an intending pupil whose anxious and interested father did not want his

Digitized by Google

boy to "waste his time learning about oxygen and hydrogen and all that" but he simply wished him to "do copper." This book is not suitable for such a one, since it is primarily intended to teach analytical chemistry. Mr. Newth has already contributed two very excellent practical text-books on chemistry of a high educational order (*vide* THE LANCET, Dec. 3rd, 1892, and Dec. 22nd, 1894), and so we were not unprepared to find the present volume on qualitative and quantitative analysis to be written on the same consistent level. Moreover, his position as demonstrator in the Royal College of Science, London, gives him authority to speak on the best methods of instilling sound ideas. The directions with regard to the carrying out of an analysis, be it qualitative or quantitative, are clear and concise, attention being very properly directed to those details of manipulation which are essential to success. The first chapter is thus devoted to preliminary exercises on filtration, solution, evaporation, fusion, precipitation, ignition, and neutralisation. This is followed by the reactions of the metallic salts, the detection of the non-metals and their acids occupying chapters XI. to XVII. which concludes Book I. In Book II. will be found the directions for carrying out quantitative work (Part I.) gravimetrically and (Part II.) volumetrically (including gas analysis), while Part III. is devoted to the estimation of carbon, hydrogen, nitrogen, chlorine, and sulphur and phosphorus in organic compounds. A section is added on miscellaneous physico-chemical determinations, such as the specific gravity of solids and liquids, boiling point, melting point, and vapour density. The appendix contains tables of data useful in analysis.

The author has made the most of the space which a comparatively small volume has afforded him and the book will be found a reliable guide and an excellent companion for work at the chemical bench.

Janus. Troisième année. Première Livraison. Juillet-Août, 1898. Amsterdam: F. Van Rossen.

THIS is the first number of the third volume of the international journal which treats mainly of the history of medicine and of medical geography. Published in Amsterdam and edited by Dr. H. F. A. Peypers of that city, it contains contributions in English, French, German, and Italian, and comprises in the list of its supporters the names of well-known physicians all over the world. A paper of much interest to the English reader is that by Dr. J. F. Payne dealing with some "Letters and Fragments of Thomas Sydenham." These are four in number—namely: 1. A private letter to his friend, Dr. Gould, Fellow of Wadham College, Oxford, dated from "*Pell Mell*, Dec. 10th, '87," or two years before the death of the writer. After informing Dr. Gould of the safety in administering opiates to a variolous patient salivated by mercury Sydenham goes on to refer to his own unpopularity (surmised by the editor, Dr. Payne, to be due to his previous connexion with the Puritan party) and to the care he had taken to write nothing beyond that which was "down-right matter of fact" based on personal observation. 2. This is a petition of "Capt. Thomas Sydenham" to Oliver Cromwell, preserved in the State Paper Office. It was written in 1653 and refers to the services rendered to the cause of the Commonwealth by the petitioner and his brothers Major John Sydenham and Major Francis Sydenham, both of whom were slain in the Civil War. The petition was favourably received, the sum of £600 being awarded to Sydenham by the Council. 3. A letter to a patient whose case was deemed by Sydenham to be "only that which in men we call Hyperchondriacall, in women Hystericall ....." advising a temporary abstinence from medicine, and then, if the symptoms continued, to make trial of Peruvian bark, at the same time expressing a wish that he (the patient) might have an attack of the gout, as being of itself a "bitter but most effectual remedy." 4. The last excerpt is from some notes in English written in 1669 and criticising somewhat freely the current practice in regard to small-pox and reiterating his confidence in conclusions drawn from his own observations. "The Plague at Formosa" is the title of a brief article by Dr. J. Matignon, and Dr. Brandt writes upon the Medical Geography of African Diseases. There is also a learned account of an Antique Vase, which is of medical as well as archæological interest, by Dr. A. Kronfeld of Vienna, and the first part of an article upon the Early Periods of Anæsthesia by Dr. Cabanès. The bibliographical and other summaries are exceptionally full and varied and the number includes several plates illustrative of beri-beri at Java, which are copied from a report by Dr. Vordermann exhibiting patients suffering from the disease, the hospitals for their reception, and the kinds of rice to which the malady is attributed.

Diseases of the Kidneys and Genito-Urinary Organs. By Professor Dr. PAUL FÜRBRINGER. Translated by W. H. GILBERT, M.D. Vol. II. London: H. K. Lewis.

THE diseases of the kidneys considered in this volume are those which depend upon suppuration, calculus, tumours, and abnormalities; the remainder of the space is devoted to diseases of the bladder, urethra, and genital organs. This volume represents a large amount of labour and is filled with the different opinions of various authorities. In dealing with the results which follow a stone in the kidney more stress might with advantage have been laid on the condition of calculous anuria which usually first comes under the notice of the physician and which requires prompt recognition if surgical treatment is to be of any avail. In discussing the various operative measures in cases of calculus the advantages of nephrotomy over nephrectomy are clearly pointed out, but it would have been well also to have made the advantages of an early operation more clear, for statistics of operations clearly show that the mortality is very much less in cases which are operated upon before any definite changes have taken place in the renal tissue itself. The affections of the genital system are very fully discussed and the different indications for treatment are clearly pointed out. This volume contains a large amount of information and will prove a very useful work to all who wish to consult the principal views which are held by the different authorities of the present day. There is an excellent bibliography at the end for those who desire further references.

The Removal and Disposal of Town Refuse. By WILLIAM H. MAXWELL, Assistant Engineer and Surveyor, Leyton Urban District Council. London: The Sanitary Publishing Co., Ltd., 5, Fetter-lane, Fleet-street, E.C. 1898. Price 15*s*.

IT will be admitted that a book which includes "a *résumé* of the law bearing on the subject, a consideration of the nature of town refuse, a discussion of the various systems of its collection, and finally an investigation of the methods of its sanitary and economical disposal, or in some cases utilisation," must cover practically the whole of the ground of one very important branch at any rate of sanitary engineering. This branch, however, does not include the very wide subject of sewerage and sewage disposal, the title which Mr. Maxwell has chosen for his book referring strictly to house, trade, and street refuse; although, again, it is difficult to separate for the purpose of classification the removal and disposal of excreta where the pail, privy, cesspool or midden system is in vogue. Undoubtedly the most interesting part of the work is that dealing with

Digitized by Google

"refuse destructors," "destructor accessories," and the economic means available for utilizing the heat of combustion of waste materials, as in the application of Mr. Halpin's system of thermal storage recently installed at the Shoreditch Destructor and Electricity Station. This installation in particular is fully described on pages 327 and 328, and the engineering principles involved in the working of this ingenious system are made perfectly clear. A more miscellaneous mixture than common house garbage can hardly be imagined, and this fact largely militates against its economic destruction by heat, not to say utilisation of what fuel value it may possess for the purpose of steam-making. But considerable advance has been made in this direction only within the last few years. It was not long ago when a great proportion of London house refuse was dumped down on almost every available open space to the exceeding detriment of the inhabitants near by and the depreciation of the property. Huge heaps have thus accumulated on the marshy grounds on the banks of the lower reaches of the River Thames. With the great increase in the metropolitan and suburban population the evil grew at an alarming pace and the problem had to be seriously faced. Engineering has been brought to bear upon the matter with success, and with few exceptions now "destructors" are at work on all sides. And these heat appliances in some instances are not mere "destructors" but "converters" also—that is, extracting and utilising, perhaps in the production of electric energy, any calorific value that the "rubbish" may possess. So far the dust problem has gone ahead of the sewage problem from the points of view of both disposal and utilisation. We venture to think that this is because the sewage disposal question, unlike that of garbage, is not exclusively one for engineers to approach. It requires the joint efforts of the chemist, biologist, and engineer. With this essential combination at work we may soon hope for a satisfactory solution of the sewage problem; and indeed very encouraging results, as is well known, have already been obtained as an outcome of the three aspects of the problem having been attacked in concert by experts severally concerned in the three branches of science just indicated.

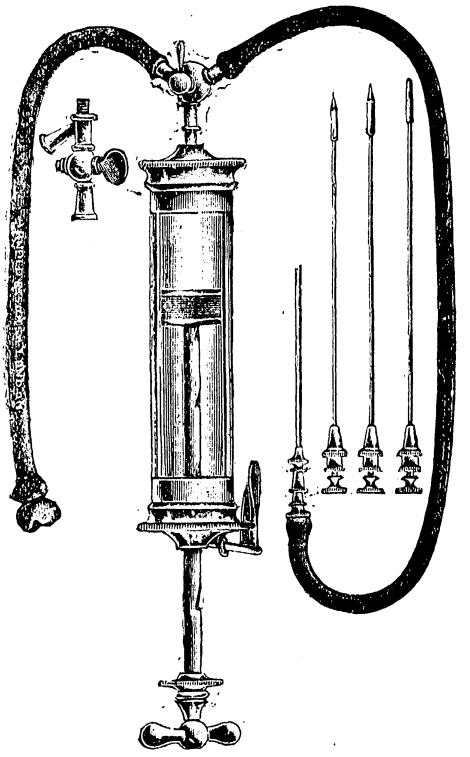
But there are other matters affecting the health and comfort of the public, and with these also Mr. Maxwell deals. Indeed, it will be seen that such a book is indispensable to our local health authorities, vestries, and similar bodies, and we believe we are right in saying that it is the first really comprehensive work on the subject. On reflection this must be so, for the material in the chapters is in the main based on quite recent advances in methods of disposal and utilisation. In the first chapter the sewerage and cleansing of streets, the question of the best materia for paving streets, and the removal of snow, are amongst the important subjects touched upon. To grapple efficiently with these problems is the duty—and it is often an arduous one—of our local authorities, who in particular owe Mr. Maxwell a word of thanks, we think, for placing at their disposal so much valuable material and information on just those subjects which are of direct practical concern to them. The book is well written, well devised, and comprehensive, so far as the subject goes—and none can dispute that the subject is a broad one. Mr. Maxwell has contributed a valuable book of reference and a guide upon a most important branch of work which is closely connected with the health and well-being of the public.

De la Symphyséotomie à la Clinique Baudelocque. Dec. 7th, 1896–Dec. 7th, 1897. By Professor PINARD. Paris: G. Steinheil.

DURING the year ending Dec. 7th, 1897, the operation of symphysiotomy was performed 7 times in the Clinic Baudelocque, making a grand total of 89 such operations performed in that clinic during the six years 1892–97. Six of the cases were examples of rickety, flattened pelves, while the remaining case was one of a Naegelé oblique pelvis. Of the mothers 2 were primiparæ and 5 multiparæ; of the former 1 died from sepsis and acute albuminuria, the latter complication being present upon her admission to the clinic. All the children were born alive, 3 being delivered by forceps and 4 by version. In one patient the operation was performed for the second time, her second pregnancy having been terminated by symphysiotomy in 1892. At the first operation a tear occurred through the anterior vaginal wall into the operation wound, and at the second operation a similar accident happened in spite of every care being taken to prevent it. The urethra and bladder, however, escaped injury and the wound healed well. In the event of this patient again becoming pregnant Professor Pinard considers that Cæsarean section would be indicated on account of the cicatricial tissue present in the anterior vaginal wall. That symphysiotomy may produce some permanent enlargement of the pelvis seems to be shown by the fact that 4 of the patients delivered spontaneously during the year had previously had symphysiotomy performed upon them. The report is of interest as enabling us to watch the progress of the operation. Professor Pinard justly points out that in any future history of symphysiotomy a very important place will have to be assigned to the work done at the Clinic Baudelocque. That the operation is now established upon a firm basis is shown, he thinks, by the fact that in the discussion at the Moscow Congress no one was found to attack the favourable opinions expressed about it by Varnier, Zweifel, and Küstner.

LIBRARY TABLE.

Transactions of the Reading Pathological Society, 1896–97.—The oldest pathological society in the United Kingdom has only issued two volumes of Transactions, of which the one under review is the second. It is edited by the President, Dr. H. Phillips-Conn, and the honorary secretaries, Dr. W. J. Maurice, Dr. Guilding, and Dr. J. B. Hurry. Eighteen articles are contributed by various members of the society. Perhaps the most interesting from a practical point of view is a note by Mr. H. G. Armstrong on the Distribution of the Rash in Scarlet Fever. He quotes sundry authorities, nearly all of whom say that the rash does affect the face, and one of whom (Aitken, 1880) says that the rash appears *first* on the face. Thomas of Leipsic says that the rash appears only on the temples and forehead and so does Fagge (1891). Mr. Armstrong has made notes of eleven cases with the result that he considers Thomas's opinion strictly correct. He says: "As the flush disappears on the termination of the fever the upper margin of the true exanthem may be seen on the neck just below the ramus of the jaw and occasionally on the temples and forehead at the roots of the hair, the lobes of the ears being almost always affected. ..... The rash of rubella ..... makes its first appearance on the cheeks and at the root of the nose." Mr. Armstrong thinks this a valuable diagnostic point. Dr. Alfred Ashby has a very interesting paper upon Small-pox and Vaccination.



ILFORD MEDICAL SOCIETY.—At a meeting of medical men held at Mr. M. J. Houghton's residence, it was unanimously decided to form a medical society for this district. Twelve gentlemen attended. Mr. Best was elected President, Mr. Drought treasurer, and Mr. H. Ernest Watts secretary. A small sub-committee consisting of the officers elected and three other members, Mr. Bell, Dr. Fraser, and Dr. Appleyard was also appointed. Meetings are to be held monthly at members' houses in rotation, when a paper is to be read, cases are to be shown, and medical topics discussed. The subscription is nominal. The first meeting will be held at the President's house, High-road, Ilford, on Oct. 6th, at 9 P.M.

New Inventions.

NEW ASPIRATOR.

MESSRS. ARNOLD AND SONS have made for me an aspirator which works on the Dieulafoy principle, but the nozzle of the pump is a three-way detachable tap, with the three branches arranged to exactly trisect a circle. A spring catch prevents recoil of the plunger and maintains the vacuum at 20, 40, 60, 80, or 100 cc. For exploration fix the syringe to the nozzle which lies in the continuity of the tubing, and close all the branches; then draw the plunger to the size of vacuum desired, insert the needle or trocar, and place the indicator between the ascending and middle branches. If there is fluid it will be aspirated into the syringe, then if the fluid appears to be such as would run by syphonage, place the indicator between the ascending and descending branches, and remove the syringe with a sample of the fluid, leaving the tubing and tap *in situ*. If syphonage should stop by blocking of the cannula or tubing, both limbs of the syphon can be flushed out with any antiseptic fluid from the syringe.

The advantages claimed for the instrument are as follows: 1. It allows the operator to establish syphonage by simply turning the indicator without disturbing the tubing. 2. It gives him complete control over the operation by placing the syringe at his disposal to flush out the tubing and cannula if necessary without admitting air or disturbing the tubing. 3. The spring-catch by preventing recoil of the plunger maintains the size of vacuum desired. 4. Exploration, syphonage, or aspiration and washing out a cavity can be carried out under the most perfect antiseptic conditions and without admitting air. 5. The plunger is always efficient and works smoothly. 6. By means of the three-way nozzle anyone possessed of an aspirating needle or a trocar with side branch can extemporise a more useful instrument than the ordinary Dieulafoy aspirator by means of a glass syringe and rubber tubing. 7. Compared with the bottle aspirator it has all the advantages of Dieulafoy's design for dealing with pus. 8. The whole instrument can be readily taken to pieces and sterilised.

Beeston, Notts. WILLIAM CATTO, M.B., C.M.Edin.

FACILITIES FOR CLINICAL INSTRUCTION IN INFECTIOUS DISEASES AFFORDED BY THE HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.

THE study of infectious disease is a very necessary part of the student's curriculum, but it is only within recent years that proper facilities have been afforded for taking advantage of the valuable material to be found in the fever hospitals of the Metropolitan Asylums Board. In former years the student had but few opportunities of becoming familiar with the natural history of this branch of medicine, and it was by no means an unheard-of event for a student to complete his career without having seen half a dozen cases of infectious disease. That there is still evidence of the state of affairs which formerly obtained may be gathered from the fact that during 1895 no fewer than 1277 patients, or a percentage on the total admission into the Metropolitan Fever Hospitals of 7·6, were, after admission, found not to be suffering from the diseases mentioned in the medical certificates upon which they were removed to hospital, the percentage of mistakes at the Eastern Hospital at Homerton being 11·0 of the total admissions. At the present time five of the admirable hospitals of the Asylums Board—viz., the Eastern at Homerton, the Western at Fulham, the South-Eastern at Deptford, the South-Western at Stockwell, and the North-Western at Hampstead, are open under certain conditions to students and medical practitioners, while instruction in small-pox is also afforded at the small-pox ships in the Long Reach, near Dartford. A student desirous of taking a course at one of the Board's hospitals must have completed his third year and have held the offices of clinical clerk and dresser; he must then obtain the sanction of the medical school to which he belongs and pay a fee of three guineas for the first three months, and one guinea for each subsequent month to the clerk of the board, from whom he receives a card indicating the hospital to which he is to be attached. At this hospital he must attend at stated times for at least two days in the week for a minimum period of two months, and on the completion of his attendance he receives a certificate from the medical superintendent whose lectures and classes he has attended. While in the hospital the student places himself under the control of the medical superintendent, and is bound to observe the regulations in force for the prevention of spread of infection. These rules comprise the wearing while within the hospital wards of brown holland overalls, consisting of coat, trousers, and cap, which are provided by the board, and the use of what may be termed a discharge block, which consists of an infected room where the overalls are left, a lavatory, and a theoretically uninfected room. The students are further required to keep their hair short and to be efficiently protected against small-pox. A duly qualified medical practitioner has equally to conform to these regulations and must obtain the consent of the medical superintendent of the hospital at which he elects to attend. The student who attends these courses will obtain a fair knowledge of infectious disease, which will stand him in good stead in years to come, while he will also get an insight into the management of fever hospitals and the methods of disinfection practised therein.

The provisions with regard to instruction in small-pox differ somewhat from the above, as it is necessary for the student to reside for from two to four weeks on the small-pox ships, where he is provided with rations, apartments, and washing at the extremely moderate sum of 12*s*. per week. The student has to travel to and from the hospital ships on the ambulance steamer and to furnish himself with a suit of clothes to which he does not attach much value, in order that it may be disinfected or destroyed at the termination of the period.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 10, 1898.

FOR those of all creeds there is wealth of material for profound thought in the admirable and comprehensive Presidential Address which Sir WILLIAM CROOKES, F.R.S., V.P.C.S., delivered before the British Association for the Advancement of Science at Bristol on Wednesday. Sir WILLIAM CROOKES has devoted his life to science and his laborious and painstaking researches have, as is well known in all scientific circles, borne abundant fruit mainly in the direction of throwing more light on the constitution of matter and on the evolution of the elements. This is not the only occasion upon which Sir WILLIAM CROOKES has addressed the British Association. More than a decade ago at a similar meeting he ventured the hypothesis of the so-called meta-elements, ascribing the apparent fluctuation of atomic weights to groups of atoms comprising, so to speak, a cluster round one common number. Then there were indications occurring in his masterly researches of the atomic value of the same element differing slightly, a circumstance which would quite account for the difficulty of raising the supposition of PROUT from the grade of hypothesis to that of a theory. The genesis of the elements, however, formed but a small part of the address at Bristol, though the President made a very important announcement as the result of the exceedingly penetrating character of his spectroscopic studies. The air just now would seem to be full of new elements, most of which appear to be of a singularly inert type; but Sir WILLIAM CROOKES announced the appearance of a new element occurring in the rare earths which he proposes to call "monium." He says it has a marked individuality, but although so young and wilful "it is willing to enter into any number of chemical alliances." He apologised for adding yet another element to an already long list, but when we regard them, he added, in the light of component parts of a dominant element, frozen in embryo, and arrested in the act of coalescing from the original protyle into one of the ordinary law-abiding families for whom NEWLANDS and MENDELÉEF have prepared pigeon-holes, they arise to supreme importance.

Recent events and public discussion of a matter of great national importance have evidently prompted the eminent chemist to choose as part of his Presidential Address the question of food supply. At the outset Sir WILLIAM CROOKES was decidedly pessimistic as to future demands being supplied by the ordinary methods of agriculture. It is the chemist, he asserts, who must come to the rescue of the threatened communities. In other words, it is through the laboratory that starvation may ultimately be turned into plenty. Sir WILLIAM CROOKES looks upon the exhaustion of the world's stock of fixed nitrogen as a matter of far greater importance than the exhaustion of British coal-fields. The former would mean not only a catastrophe little short of starvation for the wheat-eaters, but indirectly scarcity for those who exist on inferior grains together with a lower standard of living for meat-eaters, scarcity of mutton and beef and even the extinction of gunpowder. Every square yard of the earth's surface has nitrogen gas pressing upon it to the extent of about seven tons, but in the *free* state, and wheat demands it *fixed*. In the free gaseous state nitrogen is worthless, but 27 tons weight in the atmosphere combined in the form of sodium nitrate would be worth £2000. The question arises, How, then, are we to utilise the abundant element for such a mighty purpose? Sir WILLIAM CROOKES showed some time ago that the nitrogen of the air could be converted directly into nitrous and nitric acids by passing a strong induction current through ordinary air, when it takes fire and burns with a powerful flame. This inconsiderable experiment, he mentioned, may not unlikely lead to the development of a mighty industry destined to solve the great food problem. The suggestion makes the recent announcement of the alleged synthesis of albumin pale into the merest insignificance. It is all a question, in short, of power which Sir WILLIAM CROOKES seems to think Nature could be made to supply. In short, the fertiliser of the future is to be electric nitrate produced, say, by Niagara or some colossal natural force as soon as we come to know how to turn it economically to account.

Sir WILLIAM CROOKES'S observations on recent researches which have bred newly-discovered elements such as argon and helion are of interest. Referring to his own researches the President confessed he had been engaged upon "the waste-heaps of the mineral elements," but Professor RAMSAY "is dealing with vagrant atoms of an astral nature." From the discovery of new elements he then passed to new vibrations—wireless telegraphy—referring chiefly to the investigations of Signor MARCONI. This naturally led him to the Roentgen rays, the discovery of which was due to the vacuum tube bearing Sir WILLIAM CROOKES'S own name. The nature of these rays is still unfathomed. As has been shown by Dr. RUSSELL, a ray-emitting power appears to be a general property of matter, for he has demonstrated that nearly every substance is capable of affecting the photographic plate if exposed in darkness for sufficient time. The property is most marked—as we have shown in our columns—with uranium and thorium compounds.

Sir WILLIAM CROOKES, as is well known, has been bold in expressing his views on what most people consider to be occult subjects and he has been taken to task for his attitude as a scientific man on these questions. He has been silent for some time, but he evidently felt that the trend of public thought has changed, and so he reverted to a subject which has recently attracted the attention of recognised men of science. Sir WILLIAM CROOKES believes the fundamental law of telepathy to be "that thoughts and images may be transferred from one mind to another without the agency of the recognised organs of sense, that knowledge may enter the human mind without being communicated in any hitherto known or recognised ways." The subject obviously presents

Digitized by Google

many difficulties in the way of practical inquiry, investigation, and elucidation; but we do not doubt that some are prepared to accept this postulate. Molecular movements occur in the brain during thought processes and it is conceivable that physical vibrations are set up capable from their extreme minuteness of acting directly on individual molecules, while their rapidity approaches that of the internal and external movements of the atoms themselves. We need only refer to the Roentgen ray phenomena and the transmission of electric waves without wires in order to find an analogy which lends considerable assistance to the idea.

It will be conceded that in spite of the wide range of subjects which the President thought fit to include in his highly interesting address, yet he preserved with conspicuous success a continuity of reasoning and thought throughout. The subjects touched upon were such as will provide abundant opportunities for reflection for all classes of thinking people. The address bristles with some of those fascinating suggestions which have arisen as the outcome of the enormous progress of scientific research during the last few years. Sir WILLIAM CROOKES has crystallised into characteristically simple language these advances, and his eloquent peroration should afford a powerful stimulus to all those engaged in wresting the hidden secrets from Nature. "Steadily, unflinchingly, we strive to pierce the inmost heart of nature, from what she is to re-construct what she has been, and to prophesy what she yet shall be. Veil after veil we have lifted and her face grows more beautiful, august, and wonderful, with every barrier that is withdrawn."

WE have recently[1] had occasion to notice the interesting and beautiful geological model of London and its suburbs constructed by Mr. JAMES B. JORDAN, F.G.S. This gentleman is well and favourably known to meteorologists by his contributions to their branch of science, by his invention of the glycerine barometer, the daily records of which are published in the *Times*, and by his admirable photographic sunshine recorder, both of which are known by his name. He is, perhaps, better remembered by medical men as the joint author with the late Mr. WILLIAM TOPLEY, F.G.S., of the "Geological Survey of England and Wales," of the excellent geological models of the south-eastern portion of England, including the Wealden district,[2] and of the Thames Valley, which last, as Sir A. C. RAMSAY, LL.D., F.R.S., states, clearly explains the relation of the river to the geological formations through which it has cut its way from source to sea. In all these models London is well represented and this reminds us of the splendid geological model of London which stands in the Museum of Practical Geology, 28, Jermyn-street, St. James's, S.W., where it attracts annually many visitors, who, owing to its large scale—six inches to one mile—are able to satisfy themselves as to the altitude above sea level and the nature of the geological formation of any locality in which they may be interested, the names of the streets, roads, parks, &c., being legibly engraved on the map before them. Then, again, the model is so constructed that not only are the more deeply seated rocks shown in coloured sections along the four sides of the model, but mechanical contrivance is resorted to by which the separate blocks of the model into which it is divided are capable of being raised above the surface, so as to expose other sections in various parts of the London area. This model has been described by Mr. W. WHITAKER, F.R.S., in his valuable work on "The Geology of London," who also adds Mr. J. B. JORDAN'S account of the constructional arrangements which he carried out in making it. All these models, therefore, it will be at once conceived, cannot fail to impress upon the geological student the local and general facts associated with the several areas represented and consequently are of eminent service to him. But their usefulness is not confined to these geological teachings; in these days of progress in sanitary science members of our profession gladly welcome such models, as they open up a vast field of inquiry as to the relations which exist between the soils and subsoils of defined areas and the various causes of disease prevailing within them.

Let us, then, see how these geological models can be applied to the practical requirements of the medical man whilst studying the statistics of disease within the areas they represent, and for this purpose we will include the map lately published by Mr. HORACE B. WOODWARD, F.R.S., to illustrate his admirable memoir on "Soils and Subsoils from a Sanitary Point of View; with Especial Reference to London and its Neighbourhood,"[3] reviewed in THE LANCET of Feb. 5th (p. 372). The horizontal scale of Messrs. TOPLEY and JORDAN'S geological model of the south-east of England is four miles to the inch, the same as that of the index map of the Ordnance and Geological Surveys; Mr. WOODWARD'S map just referred to is on the same scale. In 1888 the Ordnance Survey Office, Southampton, issued a series of Diagrams of the Sanitary (Registration) Districts in each county of England and Wales, showing also the boundaries of the civil parishes contained in each on the same scale as the index map, the boundaries of the registration or sanitary districts being coloured red and those of borough or other urban sanitary districts brown and blue respectively. Now if a clear piece of tracing-paper or linen be taken and applied to any of these diagrams a correct copy of the boundaries of the districts can be made in red ink, and when completed applied to the map or model so as to enable us to study the geological colouring and the physical configuration of the area comprehended within the boundaries of each district as they appear to us through the transparent paper or linen on which the boundaries are defined; in some instances glass may be used when the boundaries have been drawn on it. As a matter of detail it is necessary to trace the courses of some of the characteristic rivers, such as the Thames, in the model and map selected, so as to enable us accurately to adjust the tracing to the map or model. Mr. JORDAN'S model of London and its suburbs above referred to is on the larger scale of one mile to an inch, but

the method which we have explained is equally applicable to it when the boundary lines of the several districts on the same scale have been procured. We believe that for many years the above method has been adopted by Mr. ALFRED HAVILAND in studying the medical geography of Great Britain.

It will be evident to our readers that such relief maps as we have briefly noticed cannot fail to be of great usefulness in the study of the physical configuration and geological structure of a country in relation to the causes of disease. The all-important factor in local climate—aspect—is at once grasped through their means, and all can appreciate the value of such a help in this direction; again, the pent-in valley systems, where natural air-flushing is defective on account of the obstruction offered to prevailing winds, are displayed before us as if we were viewing them from one of the surrounding heights. Eleven years ago, at a meeting of the Scottish Meteorological Society in Edinburgh, it was proposed to select sites for the outdoor treatment of the phthisical, and it was urged that the country should be well and carefully studied with the view of selecting sites for buildings devoted to this purpose; in such a selection the advantages offered by relief maps would be incalculable as they facilitate the process of eliminating inappropriate sites at once and thus afford more time for the critical examination of others which promise to fulfil the required conditions of aspect, altitude, soil and protection from adverse winds. In these days when an effort is being made to disseminate knowledge with regard to the prophylaxis of tuberculosis, which has hitherto been ever amongst us, ravaging and despoiling our population, it is to be hoped that the publication of relief maps will be undertaken by the Government and not be left to private enterprise, as hitherto has been the case. Then, again, in that wide field of research, bacteriology, these geological models present an opportunity to our profession to study the habitats of those "hidden foes" which make so great a mark on our death-rates and the natural history of which as regards their relation to soil remains as yet almost a *terra incognita*.

OMDURMAN has fallen, the Egyptian flag and the British standard are flying at Khartoum, the great Dervish army has been utterly defeated, the Khalifa is a fugitive, the neck of a cruel and oppressive tyranny has been broken, and, to the relief of all, and especially of the unhappy inhabitants of the Soudan, there is a complete and final end to the power and prestige of Madhism. Such, briefly summarised, is the welcome news from Egypt which has given rise to a sense of relief and rejoicing in this country and to much unstinted praise on the continent of Europe and in the United States of America. We do not think that the situation could be more tersely or generously stated than has been done in a Paris paper—the *Temps*—which recognises that it was a real *tour de force* to bring so far from its base into the desert, and especially by the Nile, the course of which is so frequently broken by cataracts and studded with rocks, an army perfectly equipped, in admirable training, and in the best of sanitary conditions. All had, it says, been foreseen, calculated, and regulated by the simplest means and according to a general plan so scientific that the march may be likened to the solution of a mathematical equation. That the difficulties which have been encountered in transporting a large army equipped with all the weapons and appliances of modern warfare some twelve hundred miles have been successfully overcome so that the Khalifa's army has been utterly defeated outside his capital with relatively little loss to the force under Sir HERBERT KITCHENER'S command is no doubt a striking military achievement of which any nation may well feel proud.

On the design, organisation, and conduct of the campaign, the tactical skill o the general, and the discipline and gallantry of his troops there is no need to dwell. The nation is to be congratulated on having such an army as that which fought at Omdurman and the army is to be congratulated on having found a general of such conspicuous ability as Sir HERBERT KITCHENER. But we may legitimately refer to the medical arrangements for the expeditionary force, which seem to have been admirably carried out. If our campaigns in various parts of the world since the Crimean war be compared with those of other nations the British medical service will have no cause to feel ashamed of the results of the comparison. So long as war is war and military success is necessarily its first object it is futile to expect that army hospitals can be equipped with such an elaboration of comfort as to leave nothing to be desired, nor indeed is it to be wished that soldiers on service should keep pace with the habits of a luxurious age. All that is practically attainable should, however, be provided, and we are glad to recognise that every succeeding war shows a progressive improvement in these respects. By lessons of experience we have been schooled into forethought and attention to medical and sanitary details with the result that we have been steadily but surely improving in the management of our small campaigns and military expeditions. Time is no doubt an important element, for success is in proportion to preparation. The more unexpected and sudden the outbreak of war and the more rapid the conduct of a campaign the harder it obviously becomes for all branches of the military service, and especially for the medical transport and supply branches, to fulfil the requirements of an expedition. The Soudan campaign no doubt gave time for the needful preparation, of which apparently full advantage was taken, for it is probable that no force was ever better or more completely organised and equipped in these respects than the force which went to Omdurman under Sir HERBERT KITCHENER.

We congratulate the officers of the Royal Army Medical Corps on their share in the successful issue. The total number of casualties among the Anglo-Egyptian forces at Omdurman was 387. The British killed were 2 officers and 23 rank and file, while 7 officers and 99 rank and file were wounded. 6 British officers attached to the Egyptian army were wounded—137 British casualties in all. We much regret to notice the name of Lieutenant-Colonel A. J. SLOGGETT, R.A.M.C., among the list of severely wounded and trust that he may speedily recover. Lieutenant-Colonel SLOGGETT was the senior medical officer

Digitized by Google

with the First Brigade under the command of Brigadier-General WAUCHOPE, C.B., and had been previously mentioned in despatches for his services in the Dongola campaign. Now that the Royal Army Medical Corps is for the first time an amalgamated corps we should not omit to mention that a private and lance-corporal of that corps were also among the wounded. It will be seen, at any rate, that the officers and men of the Royal Army Medical Corps run all the risks of battle in addition to those which they specially incur from the nature of their calling. Sir HERBERT KITCHENER in a telegraphic despatch from Omdurman of Sept. 4th says that "the British wounded have all left for Abadia in barges towed by steamers. I saw them before leaving and they were all doing well and were comfortable." We venture to add an expression of sympathy with the *Times* on its loss of the services of two of its war correspondents, one of whom was killed and the other severely wounded.

Annotations.

"Ne quid nimis."

THE WATER FAMINE IN NORTH-EAST LONDON.

THE situation in the district supplied by the East London Waterworks Company has not altered for the better since we described it a fortnight ago, for the heavens still refuse rain. That it has not altered materially for the worse and that the public health remains fair must be looked upon as a piece of good fortune for the company commensurate at least with the bad fortune which they are experiencing in running short of water during a drought. For if an epidemic of any kind should break out in north-east London the medical men would have hard work to keep the mischief under when deprived of the most natural and efficacious remedy against zymotic diseases—water. Proceedings are now being taken to place the mains of the company in communication direct or indirect with those of two other companies, and when this has been done all fear of an absolute water-famine will be at an end. But with the tiding over of the temporary difficulty we hope that the occurrence of these annual breakdowns will not pass from the recollection of the people of London. They ought not to occur, and if the company cannot prevent them the company would appear to be unable to carry on its business. There is an alternative. It may be said that the company can manage its works at least as well as any municipal or central body would be able to manage them, but that if there is not the water the water cannot be supplied. In this way the relations during the last two or three summers of the East London Waterworks Company with their clients form a strong argument for the augmentation or alteration of the present source of the metropolitan water-supply.

SCIENCE AND MEDICINE.

DR. KANTHACK, Professor of Pathology at the University of Cambridge, recently delivered the mid-sessional address before the Abernethian Society of St. Bartholomew's Hospital. He chose for his subject "The Science and Art of Medicine" and the whole discourse was an earnest and impassioned plea for the more scientific teaching of medicine and for the impressing upon students the necessity of finding out if possible everything about a patient which can have any bearing on the case. Dr. Kanthack drew a parallel between medicine and a technical industry such as brewing. An art, he said, may be learned in two ways: first, by experience based on a rule of thumb principle, which is the English way; and secondly, by experience based upon systematic research, which is the German way. Citing Hansen's great work in revolutionising the brewing industry at Copenhagen Dr. Kanthack proceeded to point out that the more we know about fermentation the more we shall know about disease, for infection is merely a form of fermentation. In our happy-go-lucky British fashion we do manage somehow to get good beer, though the average English ale, to say nothing of Scotch ale, is somewhat heavy for this weather. But there is one technical industry in which a real knowledge of fermentation would be of infinite assistance, and that is bread-making. Why is it that ordinary baker's bread is simply uneatable after it has been baked two days? If it were made of good flour, good water, and carefully selected yeast it should keep quite fresh three or four days. There is at least one bakery, and there may be more, which pays attention to the yeast question, but everybody knows the usual stuff proffered as "bread." To return to Dr. Kanthack. He gave as another example the work done in Denmark, a small and poor country, with regard to the great tuberculosis question and compared it with what we are doing over here. True we have had a Royal Commission which has issued a report, and so, we might add, have we had a Commission on Vaccination, but neither of them have at present had very beneficial results. "Pathology," said Dr. Kanthack, "is not a subject of secondary importance inferior to practical medicine or surgery; it is the foundation of diagnosis, treatment, and prognosis." The late Dr. James Andrew, as sound a physician as ever lived, used always to tell his clerks that there was no place for learning like the post-mortem room and his admirable clinical teaching was always based upon scientific research. Another of his maxims was that the best book on medicine was Foster's Physiology, neither can there be any doubt of the truth of this. Even since his death the opportunities and advances of scientific research have increased enormously, and we can only hope that Dr. Kanthack's words will be taken to heart not only by his student audience but by those in whose hands lies the future training of our young medical men. With all our knowledge we are still very much in the dark about the causes and processes of disease. It is the "why" we must seek for; when we have found this we shall be better able to say how to treat it and for this reason we must inculcate research upon the learner.

SALE OF DRINK TO CHILDREN.

A CORRESPONDENT writes to us referring to our annotation in THE LANCET of August 27th entitled "Drink-fetching by Children." "It may be mentioned," he says, "that two deputations, one representing the temperance party and the other the licensed victuallers, have laid their views before the Manchester city justices. The latter deputation suggested that if any such intimation were necessary it should go forth through the press and not by circular, 'that it was the desire of the magistrates that vendors of liquor, wholesale or retail, should exercise care not to serve children of very tender years and should use their influence to minimise as far as possible what the temperance party considered to be a great evil.' One of the deputation stated that the Licensed Victuallers' Association had already issued a circular urging their members not to give sweets or toys to the children sent to their houses. He also said that if one licence-holder refused to serve children his neighbour might do so. Another said the restrictions placed on licencees had been the means of creating bogus

Digitized by Google

clubs, to which 'young persons'—a euphemism probably for children—were sent for drink. The representative of Gilbey's mentioned the case of a licencee who refused to supply children under thirteen years of age and found they were sent to neighbouring clubs, so that he had through declining trade to sell his business. No doubt it is a difficult question to settle. It would be simplified if alcoholic drinks were only taken 'when necessary,' but necessity would in that case no doubt very frequently arise. The Lord Mayor complimented both deputations on the moderation with which their views had been expressed. In addressing his colleagues he said he need not remind them that there was no law to compel a publican to refuse to sell drink to children under thirteen for outdoor consumption. He assumed that they would not dream of sending out any circular instructing publicans not to supply such children, but there was no reason why they should not instruct the chief constable to issue one asking all licencees to assist the justices by refusing as far as possible to sell drink to children under thirteen. He moved the following resolution: 'That the justices of this city, assembled in special meeting for licensing purposes, desire to express their opinion, with which they feel sure all licencees will agree, that it is undesirable in the common interests of morality and good government to serve liquor to children under thirteen years of age, and most earnestly request that all licencees will assist the justices in carrying out this very laudable object to the best of their ability.' In the discussion which followed there was a general agreement with the views of the Lord Mayor. Dr. Woodcock thought that 'their first consideration ought to be, not the convenience of the parents, but the future well-being of the children.' Mr. Shann said that a statement had been made to the Licensing Committee that in three-quarters of an hour on Sunday afternoon nearly 250 children between the ages of three and twelve had been served with beer at the public-houses in one street and most of them were seen to sip the beer as they took it home. It will take a long time for the mass of the people to learn that drink is a luxury, not a necessity, not always harmless, and all the more that the legislation concerning it was enacted in pre-scientific days when it was an almost universal article of belief that alcohol in some form was a necessary of life. People take drink, of course, because they like it, the educated ignoring the evidence of its being one of the chief causes of crime and physical deterioration, while the uneducated have temptations to drink that the 'better classes' know little about."

THE SEVENTH SON.

IT is comforting to see that Board schools and the spread of education have not yet altogether killed romance. On Sept. 2nd a weaver named "Doctor" Talbot was charged at Southwark Police-court with travelling on the railway without having paid his fare. The prisoner said that "Doctor" was his Christian name and he had had it given him because he was the seventh son of a seventh son, and therefore possessed the gift of healing. This is a very old belief and was sometimes varied by being applied to a seventh male child in succession, whether or no his father had been in like case. In *Notes and Queries*, June 12th, 1852, appeared the following: "In Saltash-street, Plymouth, my friend copied on Dec. 10th, 1851, the following inscription: 'A. Shepherd, the third seventh daughter, Doctress.'" In Lupton's "Notable Things," ed. 1660, we find: "It is manifest by experience that the seventh male child by just order (never a girl or wench being born between) doth heal only with touching, through a natural gift, the king's evil, which is a special gift of God, given to kings and queens, as daily experience doth witnesse." In France, especially in the Orleans district, the seventh son is called a *marcou*, he possesses healing powers, and is marked on the left side with a fleur-de-lys. On the Border the seventh son is marked with the seven stars and it is interesting to find that individuals of this class not only possess inherent healing powers but it is the usual custom to bring them up as "doctors." Wrightson, the Wise Man of Stokesley, who flourished some seventy years ago, was a seventh son. The belief is only one of the innumerable beliefs connected with the number seven. So numerous are these that a narration of them all would fill a volume of THE LANCET, but we may mention a few of them. From the very earliest ages the seven great planets were known and ruled this world and the dwellers in it, and their number entered into every conceivable matter that concerned man. There are seven days in the week, "seven holes in the head for the master stars are seven," seven ages both for man and the world in which he lives. There were seven material heavens and in the underworld described by Dante, the great Pagan dead who were not good enough for heaven or bad enough for hell reposed in a seven-walled and seven-gated city. There are seven colours in the spectrum and seven notes in the diatonic octave and the "leading" note of the scale is the seventh. Be it noted that the seventh son is not always gifted with beneficent powers. In Portugal he is believed to be subject to the powers of darkness and to be compelled every Saturday evening to assume the likeness of an ass. Wild and dreamy as all these legends and ideas are it is not impossible that underlying an almost universal belief there should be some substratum of truth. As Sir William Crookes reminds us, there are powers and influences of which we know nothing. The eye is insensible to the ultra violet rays which yet we know to exist. To quote Epictetus, "A little soul, for a little, bears up this corpse which is man," and this earth and all upon it is but a speck of dust in the vast expanse of the universe.

BOULIMIA.

ON August 27th an inquest was held by Mr. Negus Wood at Plumstead upon the body of William Ward, aged eighty-four years, an army pensioner, who died from asphyxia. At the post-mortem examination three pieces of meat measuring in all 12 in. in length were found in the deceased's "throat." Evidence was given that the deceased was always a gluttonous feeder and in the habit of bolting his food. His daughter-in-law said that she used to mince his food, but that even then he would bolt such large spoonfuls that he had to gasp for breath. A verdict was returned of "Accidental death." Instances of ravenous appetite are not uncommon, constituting the condition known as boulimia or bulimy, moreover this craving for food substances is sometimes associated with another condition known as polyphagism, when the sufferer eats pins, string, broken bottles, and other indigestible articles. In THE LANCET for May 5th, 1894, we commented upon the death of a man in the London Hospital whose stomach was found after death to be full of a heterogeneous mass of these things. Certain tribes in South America are known as earth-eaters from the habit they have of filling their stomachs with clay, and the custom of gorging is common among peoples who live a precarious life and scarcely know from one day to another when they will get another meal. Dr. Kane relates the case of an Esquimaux who ate an enormous quantity of walrus flesh and blubber, and in 1799 there was a French prisoner in England, by name Charles Domery, one of nine brothers who with their father were all remarkable for voracious appetite. One day he was allowed as much to eat as he liked and between 4 A.M. and 6 P.M. consumed 4 lb. of raw cow's udder, 10 lb. of raw beef, 2 lb. of candles, and five bottles of porter. The narrator remarks: "It is

Digitized by Google

also to be observed that the day was hot, and not having his usual exercise in the yard, it may be presumed he would otherwise have had a better appetite." When unable to procure rational food he was accustomed to eat rats, cats, and dogs, and upon one occasion, when in action on board ship, feeling himself hungry, he began to eat the leg of a man, which limb had been shot off and was lying handy. We fancy the custom still exists in some parts of the country of having hasty pudding eating matches, and at a certain college in Oxford the following rite obtains or used to do twenty years ago. On Mid Lent Sunday the first lesson in the evening is Genesis xliii., which gives an account of Benjamin's mess, which was five times as great as any of the other's. Furmenty was always served in Hall on that evening, and the junior man at each table was considered as Benjamin and served with an enormous helping. If he ate it all he could "sconce"—i.e., fine the whole table in sherry—if he could not he was himself fined. When this custom originated no one knows, but it is probably like so many other old customs a remnant of paganism with a veneer of Christianity over it.

REPORT OF THE ASYLUMS COMMITTEE OF THE LONDON COUNTY COUNCIL.

THE ninth annual report of the Asylums Committee of the London County Council, presented to the Council on May 17th, 1898, has just reached us. The report deals with the following seven institutions: Banstead, Cane-hill, Claybury, Colney Hatch, Hanwell, The Heath (Bexley), and Horton. The most serious feature of the report is the marked increase in the number of lunatics chargeable to the County of London and its various parishes. Thus the total number on Jan. 1st, 1898, was 20,482, while on Jan. 1st, 1897, the total number was 19,937. There was thus an increase in 1897 of 545. Want of accommodation caused on Jan. 1st, 1898, 1526 lunatics to be boarded out at a cost of some £31,000 per annum, but every effort is being made to provide accommodation. Up to March 31st, 1898, 1284 lunatics were residing in asylums other than those belonging to the County of London. The total number under treatment in the seven above-mentioned asylums was 14,557 and the percentage of recoveries 7·85. We are glad to see that the salaries of the assistant medical officers have been increased, the scale of payments now being from £300 to £400 per annum for the first assistant medical officer down to £150 per annum for the fifth assistant medical officer and all appointments under. With regard to the Lunacy Bill reintroduced this session the report says: "In its present form we felt it our duty to again recommend opposition." Dr. F. W. Mott, the pathologist, whose duties were sadly interfered with by a severe attack of enteric fever, appends a most interesting report which we hope to notice more fully in a future issue. The table of the various occupations of patients shows that the largest number in any one class was supplied by, to make use of somewhat of a bull, females of no occupation. Of these there were 422. The next largest class is supplied by female servants, who number 216. Among the males labourers supplied 206; those of no occupation, 87; seamen, 24; boot- and shoe-makers, 21. There were two clerks in holy orders and one medical student. Alcoholic intemperance would seem to be the most active cause of insanity; starvation and privation give very low figures except at Claybury, where 35 patients were admitted with this as the exciting cause. Dr. Mott's report deals chiefly with the pathological features observed post mortem in cases of general paralysis. He also made some observations upon the urine and found that during the seizures of general paralysis there was often present an increase in the quantity of aromatic sulphates in the urine. Dr. Mott thinks that this may be due to tissue waste. As far as the nervous system goes, however, Dr. Wakelin Barratt examined a number of vagus nerves together with the cardiac branches of the sympathetic and with one doubtful exception found no degeneration. Degeneration of the peripheral nerves is not often found, says Dr. Mott, in general paralysis except in tabetic cases. In one case where a symmetrical bullous eruption was present there was shown degeneration of the anterior crural nerve and its corresponding spinal ganglia. Microscopic examination of the brain from patients who had died from general paralysis showed (1) bio-chemical and necro-biotic changes in the cells; (2) degeneration of the tangential system of fibres; (3) changes in the vessels and neuroglia cells. Portions of brains in which all the vessels had been ligatured in order to produce complete anæmia were also examined and changes were found in the nerve cells similar to those observed in the brains of patients who had suffered from general paralysis, except of course that there had not been time enough for the proliferation of the neuroglia cells. With regard to syphilis as a cause of general paralysis as well as of tabes dorsalis Dr. Mott found that in some interesting cases of general paralysis which he examined he could generally obtain a history of venereal infection. In 10 cases of juvenile general paralysis 8 showed undoubted signs of congenital syphilis. Atheroma is common in general paralysis, but cerebral hæmorrhage is very uncommon. This Dr. Mott attributes to the fact that cardiac hypertrophy is uncommon also. Another disease rarely seen in asylum practice is hepatic cirrhosis, although abuse of alcohol admittedly plays a large part in the production of insanity. Dr. Mott considers that the patients admitted to asylums suffer from an hereditary neuropathy and that alcohol produces toxic effects upon their nervous system long before cirrhosis of the liver can be brought about. Syphilis is by far the most important cause of organic brain disease in persons not much past middle life. It acts in various ways: (1) by causing specific arteritis, (2) by causing meningitis, and (3) by the formation of gummatous growths.

SUPPURATIVE SPLENITIS.

IN the *Maryland Medical Journal* of August 13th Dr. B. M. Cromwell, of Eckhart Mines, Maryland, describes a case of suppurative splenitis caused by tight-lacing and violent exercise, which was successfully treated by operation. The patient was a strong, healthy girl, seventeen years of age, who in order to escape an impending shower ran for the greater part of a mile on a hot day in August, 1897. After running for some time she felt a pain in her left side, and reached home in a state of more or less collapse. The pain ceased before she reached home and did not return until the next day, after which it was continuous. Dr. Cromwell, on examining her two or three days afterwards, found a deep sulcus about the margin of the ribs, and in answer to his inquiries the girl explained that while she was running her corset was loose enough but the band of her petticoat was too short and she had to pull it very tight to button it. Above and below the sulcus there was a marked tumefaction. Percussion revealed dulness over the whole of the left side, extending to near the brim of the pelvis and anteriorly to near the median line of the abdomen. The edge of the tumefied spleen could be plainly felt around the greater part of this dull space. The diagnosis was an enlarged and inflamed spleen, and as no improvement followed from iodine ointment and blistering an incision was carried through the abdominal parietes into the substance of the spleen. At first there was a copious flow of bright arterial blood, then a small ribbon of pus was mixed with it, and as the pus increased in quantity the blood diminished until the escaping fluid consisted entirely

Digitized by Google

of pus, which continued to be discharged for many days under the influence of poultices, and for several days after it ceased there was a discharge of serum. The total amount of blood, pus, and serum was estimated at about 30 oz. The girl made a good recovery and is now in excellent health.

EVIDENCE AT INQUESTS AS TO CAUSE OF DEATH.

ON Sept. 2nd Mr. J. E. Hill, deputy coroner, held an inquest at Huddersfield upon the body of Hervin Hoyle, who died after being crushed by the fall of a door in a mill. The door in question was a sliding one hung by a counterpoise. Deceased was trying to pull it down when it suddenly descended with great force and deceased was caught underneath it. The door caught him across the chest and he called for help, but he died ten minutes after he was got out. Evidence was given that the chain of the door had slipped off the pulley. Another witness said that he had examined the place of the accident and could not arrive at its cause. The cream of the evidence, however, is the following, which we give together with the verdict in the words of the *Huddersfield Weekly News*: "Sarah Jowett, who laid out the body, said the spinal cord was broken." The jury returned a verdict, "That the deceased died from fracture of the spine, caused by the accidental falling of a door." Apparently no medical evidence was called at this inquest, and although Sarah Jowett may be able to say as her great namesake was made to say in the oft-quoted lines—

> "My name is ..... Jowett;
> Whatever is known, I know it,"

yet we do not think that her evidence is enough to satisfy scientific requirements.

THE JOYS OF PLAGUE NURSING.

WE should like to know why it is that a vestry or a municipality though it may be composed of gentlemen in its units seems to act in its corporate capacity in a manner in which no gentleman would ever think of doing and also in a hopelessly unbusiness-like fashion. The subjoined rules have been issued for the guidance of the Nursing Sisters who are helping to combat the plague in Calcutta and are printed as reported in the *Bombay Gazette* of July 11th:—

RULES FOR THE GUIDANCE OF LADY DOCTOR AND SISTERS.

The lady doctor is responsible to the medical officer of health and the chairman of the municipality for the good conduct of the establishment, and it is trusted that the sisters will cordially support her.

2. Sisters wishing to communicate with the authorities must do so through the lady doctor.

3. Sisters must be in to dinner every night and must not leave the premises after dinner, except with the leave of the lady doctor. Such leave will not be granted more than once a week and then only till 11 P.M., except under very special circumstances: the address at which the sister will be must be given to the lady doctor.

4. Sisters going out driving are required to let the lady doctor know their destination and their escort (if any): and she is given authority to modify the arrangements made, if she shall deem it necessary.

5. Visitors to the sisters must send in their card to the lady doctor.

6. Sisters to be in bed by 11 P.M.

7. In case of sickness the lady doctor is to be at once informed and she shall, if she shall deem it necessary, or if the sisters shall desire it, call in one of the senior medical practitioners of Calcutta; she shall also make such arrangements for the invalid as shall appear necessary, with the advice of the medical attendant, subject to the approval of the medical officer of health.

8. The household expenses are to be provided for by a fixed contribution from each person to be made as soon as the monthly salaries are paid. The payment to be made through the lady doctor.

9. At present each person is to contribute Rs.110 a month for board, lodging, light, and fuel and use of the servants provided by the landlady.

10. Personal servants, punkhawallahs, ice, and wines and aerated waters, dhobee and ghari hire to be provided by each person for herself.

11. There must be at least one personal servant between every two or three sisters; some public duty may be required from such servants at the discretion of the lady doctor.

12. No orders to be given by the sisters to any except their own personal servants and punkhawallahs except through the lady doctor.

13. Any complaints about the housekeeping to be made through the lady doctor.

14. Visitors may be invited to afternoon tea with the consent of the lady doctor. Ladies may occasionally be invited to other meals (with the consent of the lady doctor), at the expense of the person who invites them.

15. The rooms to be allotted at the discretion of the lady doctor, who may subsequently alter the arrangements, if she shall consider advisable.

(Sd.) R. T. GREER, Acting Chairman.

These ladies, be it remembered, have gone out to nurse plague patients and thus assist the municipality in a very sore strait. We should have thought that the powers that be would have tried their utmost to make things as easy as possible for people who have undertaken a very arduous task; but, on the other hand, these willing servants are hampered with the most absurd rules and saddled with expenses, not merely for luxuries, but for necessaries, to enable them to carry out their duties. We do not so much take exception to the restrictions on personal liberty and the rule that nurses should say where they are going, for this may be necessary for the purposes of organisation. But it is monstrous that they should have to pay for their own board and lodging, and still more for the items mentioned in Rule 10. A punkhawallah is a necessity in India, so is a washerman. Of course all expenses should be paid as well as a salary given. The municipality may well bear in mind the fate that overtook a sheriff in West Africa the other day. Three murderers had to be executed, and not being able to hire a professional slaughterer he had to hang the criminals himself. Soon afterwards he died from shock. If the municipality have to nurse plague patients themselves we should be sorry for the patients, but plague is no respecter of persons and might not spare even a vestryman.

THE MEAN ATMOSPHERIC PRESSURE AND TEMPERATURE OF THE BRITISH ISLANDS.

APART from its purely scientific interest, the subject of climatology has special attractions for the medical profession on account of its obvious bearing on many problems of health and disease. Most persons, also, who are free to choose their place of residence like to have some idea of the kind of weather which is likely to prevail in localities where they think of settling, for there is no doubt that all places are not alike in this respect and that the fact may be shown numerically by observations continued over a sufficiently long period. As mentioned in Dr. J. W. Moore's address on the Climatology of Dublin, published in THE LANCET of Aug. 27th, the temperature and rainfall of a given town or place are among the most important meteorological factors in the determination of its climate, hygienically considered; whilst, on the other hand, it is found in most parts of the world that the variations in atmospheric pressure as shown by the barometer have a definite relation to the phenomena of either wind or rain or both of them. In his well-known work "British Rainfall," Mr. G. J. Symons, F.R.S., has fully dealt with that component of our weather, and a valuable monograph on the mean atmospheric pressure and

Digitized by Google

temperature of the British Islands has this year been published in the *Journal of the Scottish Meteorological Society* by Mr. Alexander Buchan, LL.D., meteorological secretary of the society. The comprehensiveness of Mr. Buchan's work may be understood from the fact that it is based on the compilation and reduction of observations taken at 400 stations, 176 in England, 194 in Scotland, and 30 in Ireland. Fifteen years ago he published in the society's journal two papers on the same subject, based on the observations made during the twenty-four years ending with 1880, but since that time a large number of highly important stations have been added, including the two observatories on Ben Nevis, and a better inspection of stations has been brought about. These circumstances have suggested a revision of the work, and accordingly the present paper has been prepared from the observations made during the forty years from January, 1856, to December, 1895. It consist of twenty-three pages of tabular matter, twenty pages of explanatory text, and twenty-six coloured maps of the British Islands, showing the mean temperature and pressure for each month of the year graphically by isothermal lines marked with Fahrenheit and Centigrade degrees and isobaric lines marked with inches and millimetres. Mr. Buchan says of the south coast:—

It follows that where a winter climate is sought offering in the highest degree anywhere afforded by the British Islands the combined qualities of mildness and dryness, such a climate is to be found on the shores of the Channel from about Dover to Portland. To the west of Portland and round the coast to Clifton a higher temperature may be had, but the rainfall is greater, the climate damper, and raw weather of more frequent occurrence. On the other hand, in the eastern counties north of the Thames the climate is as dry, or rather dryer, but it is accompanied by a temperature from 2·0° to 3·0° colder. The south coast has another climatic advantage which may be noted. The prevailing west-south-westerly winds having crossed the Isle of Wight pass on in the direction of London. Now observations show that in passing from the Isle of Wight to London the mean temperature falls 3·0°, the lowering of the temperature being caused by the more rapid rate by which, as compared with the sea, the land is cooled by terrestrial radiation in winter. From this lowering of the temperature in proceeding inland it follows that haze and cloud are formed with greater frequency and of greater denseness as the winds successively advance on the colder districts. Hence the skies of the south coast may be expected to be clearer and brighter than in the valley of the Thames, a statement observation amply confirms."

SCARLET FEVER IN SWINE.

THE susceptibility of any of the lower—especially the domestic—animals to specific diseases proper to man, whether the communication be effected by ordinary contagion or by artificial inoculations, is fraught with scientific and practical interest, bearing as it does on the origin of local outbreaks and the spread of disease by milk, &c., and also as affording the only practicable means of fully investigating their etiology and prophylaxis by experiments *in corpore vili*. It has thus been fairly proved that cows are susceptible to scarlet fever, though in a modified form, dependent on histological and other differences, transmitting it again to man, in whom it resumes its normal characteristics. The disease of swine known as *rothlauf* in Germany, and as *rouget* in France is in England popularly called "pig's scarlatina" on account of the red erythematous eruption on the skin, but the absence of renal phenomena and the fact that lesions of the intestines are an essential feature would suggest a nearer relation to enteric fever. But Behle[1] reports a remarkable outbreak of what appears to have been the true human scarlet fever in swine. He states that in a district where *rothlauf* had never been known a severe epidemic of scarlet fever among the children was followed or accompanied by a very fatal disease among the pigs at the same farmhouses and cottages. The symptoms included erythema, angina, albuminuria, and those of uræmic poisoning, which (or the angina) were the usual causes of death, while in such as recovered desquamation of the skin was well marked. The lesions in the kidneys observed after death were very characteristic. A previously healthy pig having been inoculated with the blood of a child suffering from a severe attack died after a week's illness with symptoms and post-mortem appearances which were identical with those seen in the human subject and in the animals which had contracted the disease presumably from the children or from one another. If the facts be correctly reported the conclusion that swine are susceptible to true scarlet fever is irresistible.

THE AUTUMN CONGRESS OF THE SANITARY INSTITUTE.

THE Autumn Congress of the Sanitary Institute will be held at Birmingham from Sept. 27th to Oct. 1st inclusive. The reception, the public luncheon, and the opening of the Health Exhibition will take place on Sept. 27th, when the inaugural address will be delivered by Sir Joseph Fayrer, K.C.S.I., F.R.S. Sept. 28th, 29th, and 30th will be devoted to the business of the sections, but on the last-mentioned date several excursions are announced. Saturday, Oct. 1st, will be entirely devoted to excursions, including one to Stratford-on-Avon and Warwick Castle. Copies of the programme, tickets of membership, lodging lists, and all other information can b obtained from the honorary local secretaries, Dr. A. Bostock Hill, Mr. W. Bayley Marshall, M.Inst.C.E., and Mr. J. E. Wilcox, A.M.Inst.C.E. Communications should be addressed to the Council House, Birmingham.

"CONSCIENTIOUS BELIEF."

WHAT is "conscientious belief"? and what is the meaning of the law when it stipulates that magistrates shall be "satisfied" of its existence in an objecting parent? The metropolitan magistrates in conference have decided to hear such applicants without requiring them to be sworn. If *satisfied*, upon a verbal statement, that the applicant had a conscientious objection, the certificate, for which the applicant would be required to pay a fee of 1*s*., would be given. Such is the decision of the stipendiary magistrates and we may be pretty sure that the Justices of the Peace for the metropolis will not act very differently. But the fact remains that the Vaccination Act of 1898 is rather hard on the magistrates and throws upon them an undignified and an impossible duty. They are to "satisfy" themselves that the belief against vaccination is conscientious; but it is understood—Mr. Balfour said so in the House of Commons—that it was not intended that the magistrate should cross-examine the objecting parent of the "conscientiousness" of whose belief he was to "satisfy" himself. It is as difficult to ascertain the conscientiousness of a belief as its intellectual ground, but it might well puzzle even a philosopher like Mr. Balfour to do either when the mouth of the magistrate is supposed to be shut. One witness before a London magistrate has given in the course of the last fortnight the following reasons, among others, in support of his "conscientious" objection to have his two children vaccinated: "That vaccination was invented by an unqualified doctor's assistant named Jenner as a 'cure all, not as a specific remedy, for small-pox," and "that the statistics of small-pox in the county of London are systematically falsified by the way in which returns of small-pox are entered." Surely the magistrate's "conscience" might have some qualms in permitting such libels of Jenner and

Digitized by Google

of the authors of the statistics of small-pox of the County of London, much less in accepting such statements as signs or proofs of a conscientious belief. We are not intending to advise magistrates to raise difficulties in giving objectors the advantage of the Act; by doing so they would accept a responsibility which is not theirs and possibly put themselves into a still more undignified position than that in which the Act has placed them. But it does not follow that they should be speechless while the greatest medical authorities are being traduced and misrepresented, or that they should fail to show that they are noting the nature of the objection on which a "tremendous experiment" is being tried on helpless children which may have to be ended some day when its significance is realised by a community still largely protected by vaccination.

ALLEGED DEATH FROM WEARING A DYED STOCKING.

ON August 23rd the city coroner for Hull concluded an inquiry into the death of Rachel Binnington, who died on August 15th from, it was supposed, poisoning contracted from a dyed stocking worn on her left leg. Medical evidence showed that the deceased died from acute septicæmia. She had very extensive varicose veins. The city analyst said that the dye was composed of logwood and bichromate of potash. Dr. H. Robinson said he did not think the dye had anything to do with the death—he would rather put it down to some septic material from a living organism being introduced into the stocking. Considerable irritation has often been set up by dyes but in such cases arsenic has been the offending agent. Some instances were reported in the columns of THE LANCET, vol. i., 1886, page 432. Bichromate of potash certainly is poisonous but it would not set up septicæmia. We cannot but think, however, that all articles of wearing apparel, at any rate those that come in contact with the skin, should never be dyed with anything but vegetable or animal dyes and should be fixed with some non-poisonous salt like alum. An exception might be made in the case of using an iron salt to produce a black dye, but certainly aniline and arsenical colours should be avoided.

THE LATE DR. K. N. BAHADHURJI.

WE recently announced in our columns the too premature death of this very able Parsee medical man. On this side of the water Dr. Bahadhurji was perhaps best known as an ardent but temperate advocate for medical reform in India, but this was far from being the only subject in which he took an interest. During the plague epidemic he started a plague hospital in Bombay and it is to be feared that though he did not die from actual plague, yet the exertions which he made in attending his less fortunate brethren who were affected contributed to hasten his death. So much was his work appreciated by his fellows that in November, 1897, he was presented by the Parsee community with a service of plate. When the news of his death was made public the Corporation of Bombay adjourned their meeting out of respect to his memory and both Europeans and non-Europeans paid him tributes of respect. His funeral was almost of a public character and the office of the Empire of India Life Assurance Company, of which Dr. Bahadhurji was the chief medical officer, and the Ripon Musical Club were closed out of respect to the memory of the deceased. The Government paper and share markets were also closed on account of the useful services rendered by Dr. Bahadhurji to the Millowners' Association in 1891 in connexion with the Indian Factory Act. In this case the prophet was certainly not without honour in his own country and we can only offer our sympathies to all his friends and relations in their sorrow and add that as members of the medical profession we mourn the loss of one who had done, and if spared would have continued to do, such excellent work.

THE BRITISH ASSOCIATION.

BRISTOL is this year the scene of the annual meeting of the British Association for the Advancement of Science, and the proceedings were opened on the evening of Sept. 7th at the People's Palace. The recent disastrous conflagration at Colston Hall, where the meetings were to have been held, caused less inconvenience than might have been anticipated, owing to the energy of the local committee in making other arrangements at very short notice. The retiring President, Sir John Evans, introduced his successor, Sir William Crookes, whose presidential address will be found in another part of our present issue. The report of the council of the Association was read and adopted at a meeting of the general committee, held at the Museum, and presided over by Sir John Evans. Professor Rücker, the general treasurer, in presenting his report for 1897–98, mentioned that the association would give a donation of £120 to the Colston Hall Fund.

CONGENITAL FACIAL PARALYSIS.

AT the recent Congress of Physicians in Hamburg Dr. Nonne related the case of a child, two years of age, who had suffered since birth from the signs of right-sided facial paralysis. The labour was normal and no artificial aid was necessary. The deformity of the face was noticed as soon as the child cried. Syphilis and alcoholism in the parents could be excluded and no anomaly could be felt in the parotid region of the affected side. The child heard equally well on each side and no abnormality of the ears was apparent. There was no affection of any other cranial nerve, and mentally and physically the child seemed perfectly well but for the facial weakness. In the region of the forehead, eye, and cheek the electrical reactions seemed to be quite abolished; but in the quadratus menti and the orbicularis oris on the affected side a strong current evoked a slight contraction. Dr. Nonne was of opinion that the defect depended upon some lesion of the facial nucleus, possibly as Moebius and others have conjectured some congenital anomaly of the ganglion cells, and the prognosis as regards any improvement was distinctly bad.

THE DANGERS OF FOOD.

THE following is a selection of headings which appeared in the daily newspapers in the brief period of 5 days from August 25th to 30th inclusive: "Poisoned by Tinned Rabbit"; "Milk Adulteration in London"; "Dangers of Tinned Salmon: Fatal Result"; "Unsound Meat in Salford: Potted Meat Manufacturers Heavily Fined"; "Poisoned by Plums"; "Heavy Fine for Exposing Diseased Meat for Sale"; "Diseased Livers and Meat Extract"; and "A Job Lot of Condensed Milk." We need not dwell at any great length on the cases of poisoning by rabbit and salmon, which may be explained by the existence of some kind of ptomaines, those obscure basic bodies which for a reason not very clear develop in what is otherwise to all appearance food of a wholesome character. In regard, however, to tinned food the public cannot be too often warned that such food should be consumed immediately after the tin is opened and on no account should the contents of the tin be regarded as fit to eat if the ends are bulging outwards or convex. It is a pretty safe indication of the wholesomeness of the contents when both ends of the tin are partly collapsed inwards. The poisoning by plums was traced to the use of a zinc pan in the stewing of the fruit. When, however, we come to consider cases in which unwholesome, nay, putrid, meat and animal organs are found in the possession

Digitized by Google

of manufacturers of "table delicacies" we are face to face with a matter fraught with the gravest possible consequences. On the premises of certain dealers were found recently forty-four barrels of livers of various animals, perished, diseased, and rotten, and the slime into which they had liquefied by putrefaction was most offensive. These dealers are described on their business card as "manufacturers of preserved provisions, soups, and all kinds of table delicacies." Of course there was no intention to employ these livers in the manufacture of food for human (or other) consumption, but the association of "table delicacies" and putrid animal organs on the same premises is not a pleasant one. Apart altogether from sentiment the mischief done might be incalculable. It is well known that putrid meat infusions, and especially putrid animal organs, yield crystallisable bodies of a very deadly nature and comparable to the powerful vegetable alkaloids such as atropine, strychnine, and digitaline.

THE DINNER TO PROFESSOR VIRCHOW

As our readers are already aware the medical profession has decided to entertain Professor Virchow at dinner. The invitation has now been definitely accepted by the distinguished guest, and already there are 195 names on the stewards' list of persons desirous of attending to do honour to their great *confrère*. The dinner will be held, as previously announced, on Wednesday, Oct. 5th, in the Whitehall Rooms of the Hôtel Métropole, with Lord Lister in the chair. There will be accommodation found for about 250 guests, a fact of which those who wish to be present and have not already applied for tickets are reminded. All communications should be made to Mr. Andrew Clark, 71, Harley-street, W., who has undertaken the duties of honorary secretary of the dinner. The inclusive cost of a ticket is £1 5*s*.

ABSCESS OF INTERNAL CAPSULE.

IN the Biological Section of the Congress of Physicians at Hamburg in June last Dr. Sänger related a case possessing both medical and surgical interest. The patient was a man, aged twenty-eight years, who had previously been in hospital on account of alcoholism and delirium, but who, in May of the present year, sought admission on account of headache, giddiness, and sickness. In May of 1897 he had had double otitis media, and in October his right ear had been operated upon. In December he had had severe pain in the frontal region which had persisted both night and day for some time, but had been relieved by antipyrin and local measures to the ear. On May 12th on admission he was rather stupid with weakness all down the left side, blunting of sensibility, hemianopia, and tenderness on percussion over the right frontal and temporal regions. There was unsteadiness in walking and even in standing and it was evident that there was a lesion of the hinder part of the internal capsule. Trephining was done, but in spite of many punctures no abscess was found. The patient died seven days later and at the necropsy an old abscess was found in the locality indicated. It had so thick and firm a wall that the exploring needle had apparently glided off and failed to penetrate it—a possibility in such cases well worthy the attention of surgeons.

BY Royal Warrant dated India Office, August 26th, 1898, it is announced that Her Majesty has deemed it expedient to alter the ranks of the officers of the Indian Medical Service. The same military titles as those conferred on the officers of the Royal Army Medical Corps are announced for the officers of the Indian Medical Service.

A MOVEMENT has been set on foot to place a memorial window to Principal Caird's memory in the Bute Hall of the University of Glasgow. We commend the idea to the notice of Glasgow graduates, who should send their contributions to Mr. Archibald Craig, of 156, St. Vincent-street, Glasgow.

THE Lord-Lieutenant of Ireland has appointed Mr. John Lentaigne, F.R.C.S.I., to be surgeon to the household in the room of Mr. Thomas Nedley, M.D. Aberd., F.R.C.S. Irel., resigned.

PROFESSOR CORFIELD has, we regret to learn, sustained a fracture of one of the metacarpal bones of the left hand by a blow from a golf-ball.

DR. KESER, Physician to the French Hospital and Dispensary, has been made a Knight of the Legion of Honour.

TYPHOID FEVER IN BELFAST.

THE main discussion at the meeting of the city corporation of Belfast on Sept. 1st was the present increased prevalence of typhoid fever. The report of the medical officer of health brought out the serious fact that between July 17th and August 20th 1052 cases of zymotic disease had been notified and of these 784 were typhoid fever. Since the notification of the Infectious Diseases Act came into force the number of cases of typhoid fever notified has been as follows:—1897: March, 215; April, 289; May, 517; June, 262; July, 179; August, 304; September, 379; October, 354; November, 351; and December, 273. 1898: January, 288; February, 222; March, 345; April, 469; May, 254; June, 327; July, 226; and August, 784 (five weeks). These figures show that, as THE LANCET Special Sanitary Commissioner in his reports on Belfast has pointed out, typhoid fever in that city is really endemic and that the present state of affairs is not an epidemic but simply an exacerbation of the normal condition. It is interesting to note that while the number of cases of typhoid fever has more than doubled (comparing August, 1898, with the same month in 1897), the number of deaths from all zymotic diseases is less by 25 per cent. In the face of the present deplorable state of affairs we are glad to say that the Public Health Committee have decided:—1. To appoint Dr. Lorrain Smith to examine bacteriologically all samples that the medical officer of health considers necessary for the purpose of investigating the cause of the fever. 2. They have decided to establish refuse destructors which should have been in use many years ago. 3. They recommend that proceedings be taken against each individual owner of houses which are not supplied with water-closets and have not back passages by which offensive material can be removed, and also to compel the provision of water-closets in place of privies. It is a most extraordinary circumstance that the corporation ever should have passed the plans of houses without back passages. 4. Each member of the corporation is to be supplied with a copy of a return of the piggeries kept in the city of Belfast and the number of pigs kept and where they are or are not kept in accordance with the by-laws. Further, the chairman of the Town Improvement Committee announced that after Sept. 5th building inspectors would test all drains of houses before they were passed. It appears that hundreds of new houses, as stated by members of the corporation, were passed without the ordinary test. Councillor O'Neill, M.D. R.U.I., said that he did not want to make out things blacker than they were—they were quite black enough in the city—but he considered it a matter of urgency that there should be an investigation of the drains of all the houses built within the past five years. "Typhoid fever was now so prevalent because," he said, "they had laid the means of breeding it. They had allowed matter containing the germs of the disease to be sown broadcast and now they attributed to a visitation of Providence what was really due to a want of visitation by the sanitary inspectors." We give the Public Health Committee every credit for the exertions they are now putting forth, but they

Digitized by Google

must remember that they have not merely to stamp out the present epidemic of typhoid fever, but they have to attack a much more difficult and more serious problem, and that is the fact that the disease is endemic and that this has been caused by a deplorable neglect of the most obvious sanitary laws. Alderman Graham, M.D.R.U.I. (chairman of the Public Health Committee), who is taking the utmost pains in the present most difficult position, deplored that the corporation had done very little for them except when there was an epidemic; he hoped they would now give them a free hand over everything they asked.

We are sure that Alderman Graham will have the unanimous support of all the citizens in any efforts he may make to have the reproach removed from Belfast that its death-rate from typhoid fever — a preventable disease—is the highest in the three kingdoms. Some people have raised suspicions as to the water being the cause of the epidemic. We quite admit that the water supplied to the city is not by any means a first-class one nor are the catchment areas beyond the suspicion of sewage contamination; but it is a curious fact that while the water comes from two different areas, no one of these supplies seems to have infected those using it more than the other; the typhoid fever is all over the city; but, what is very remarkable, the inhabitants of the gaol and the asylum (although using town water) have escaped the disease. But even if the water could be proved not to be good we know that in a few years the new supply brought from the Mourne Mountains will be ready. The Water Commissioners are pushing on with this new scheme; it behoves the corporation to do their duty and to see that the defects of the most obvious sanitary laws which they allowed to occur are at last corrected. Councillor O'Connell, M.D.R.U.I., a member of the Health Committee, said in the discussion that as a matter of fact the schemes at present in operation and contemplated would involve an expenditure of £150,000 to the ratepayers and private property owners, and he gave the following quotation from the report of THE LANCET Special Commissioner, who wrote a series of articles last year on the Sanitary State of Belfast—"Though there are all sorts of side issues and contributory causes the high death-rate and the exceptionally insanitary condition of Belfast are in the main due to the condition of the house property and thus it is that typhoid fever is endemic at Belfast.

OPENING OF THE MEDICAL SCHOOLS.

WINTER SESSION, 1898-99.

St. Bartholomew's Hospital.—The session will open on Oct. 3rd, and the usual dinner of old students will be held in the great hall of the hospital on Oct. 4th.

Charing-cross Hospital.—The session will commence on Oct. 3rd, when Professor Virchow, Foreign Member of the Royal Society, Director of the Berlin Pathological Institute, and some time Rector Magnificus of the University of Berlin, will deliver the second Huxley Lecture on Recent Advances in Science and their bearing on Medicine and Surgery. The chair will be taken at 4 P.M. by Lord Lister, President of the Royal Society.

Guy's Hospital.—The session will begin on Oct. 3rd.

St. George's Hospital.—The session will commence on Oct. 1st, when an introductory address will be delivered by Mr. George R. Turner, surgeon to the hospital, at 4 P.M.

King's College Hospital.—The session will begin on Oct. 3rd.

The London Hospital.—The session will commence on Oct. 1st. The annual dinner will be held in the College Library on Oct. 3rd, Mr. Mansell Moullin in the chair.

St. Mary's Hospital.—The session will begin on Oct. 3rd with an introductory address at 3 P.M. by Dr. Caley. The annual dinner will be held in the evening at the King's Hall, Holborn Restaurant, Mr. J. N. Moore, J.P., in the chair.

The Middlesex Hospital.—The session will open on Oct. 3rd, at 3 P.M. Dr. Arthur F. Voelcker will deliver an introductory address, after which the prizes gained during the previous year will be distributed. The annual dinner of the past and present students and their friends will take place the same evening at the Café Royal, Regent-street, at 7 o'clock, the Right Hon. Sir Ralph Thompson, K.C.B., in the chair.

St. Thomas's Hospital.—The session will commence on Oct. 3rd, when the prizes will be distributed at 3 P.M. by the Right Rev. the Lord Bishop of Rochester in the Governors' Hall. The old students' annual dinner will take place the same evening in the Whitehall Rooms of the Hôtel Métropole at 6.30 for 7 P.M., Dr. Leonard W. Sedgwick in the chair.

University College Hospital.—The session will be opened on Oct. 3rd at 4 P.M., when an introductory lecture will be delivered by Mr. Sidney Spokes, dental surgeon to the hospital. The annual dinner of the old and present students will take place on Oct. 3rd at the Hotel Cecil at 6.30 P.M., Professor F. T. Roberts, M.D. Lond., in the chair.

Westminster Hospital.—The session will begin on Oct. 3rd.

London School of Medicine for Women (Royal Free Hospital).—The session will open on Oct. 3rd. The introductory address will be delivered by Dr. J. Walter Carr, senior physician to out-patients, Royal Free Hospital, on Oct. 4th, at 8 P.M., when the distribution of prizes by Mrs. Charles Burt will take place.

The Dental Hospital of London, Leicester-square.—The session will commence on Oct. 3rd.

National Dental Hospital and College, Great Portland-street, W.—The session will begin on Oct. 3rd.

PROVINCIAL.

Mason University College, Birmingham.—The session will commence on Oct. 1st. Professor Michael Foster, M.A., M.D., F.R.S., will deliver an address.

University College, Bristol.—The session will commence in October.

University College of South Wales and Monmouthshire, Cardiff.—The session will commence on Oct. 3rd, when the opening address will be delivered by Dr. Robert Saundby.

The University of Durham College of Medicine, Newcastle-upon-Tyne.—The session will be opened on Oct. 1st, when the scholarships and prizes will be presented by Sir David Dale, Bart., D.C.L., J.P., D.L.

The Yorkshire College, Leeds.—The session will open on Oct. 3rd, when an address will be delivered by Dr. Cullingworth.

University College, Liverpool.—The session will commence on Oct. 1st.

Owens College, Manchester.—The session will commence on Oct. 3rd.

University College, Sheffield.—The session will commence on Oct. 3rd, when the introductory address will be delivered by Dr. Wm. Dyson, B.A., Vice-President of the College, Professor of Medicine, and Senior Physician, Sheffield Royal Infirmary.

SCOTLAND.

University of Aberdeen.—The session will commence on Oct. 19th.

Anderson's College Medical School, Glasgow.—The session will be opened on Oct. 20th.

University of St. Andrews.—The classes will be opened for the session on Oct. 12th.

University College of Dundee.—The session will open on Oct. 12th.

University of Edinburgh.—The session will open on Oct. 18th.

University of Glasgow.—The session will be opened on Oct. 20th.

University of Glasgow (Queen Margaret College).—The session will begin on Oct. 20th.

St. Mungo's College and Glasgow Royal Infirmary.—The session will be opened with an Address to Medical Students on Oct. 20th.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

THE Secretary of State for the Home Department has made the following further appointments of medical referees under the Workmen's Compensation Act, 1897, for Scotland:—

Sheriffdom of Lanarkshire.—Dr. Hector Cameron, Dr. T. K. Dalziel, Dr. G. T. Beatson, Dr. Duncan Macartney, Dr. James C. Renton, Mr. H. E. Clark, Dr. David Newman, and Dr. W. J. Fleming, all of Glasgow; Dr. James Barras, Govan; and Dr. Hugh Arthur, Airdrie.

Sheriffdom of Argyll.—Dr. Dove M'Calman, Oban; Mr. James Stewart, Inveraray; Dr. John Ritchie, Dunoon; and Dr. John Cunningham, Campbeltown.

Sheriffdom of Perth.—Dr. Robert Stirling, Perth; Dr. Charles Lunan,

Digitized by Google

Blairgowrie; Dr. John Mackay, Aberfeldy; Dr. Alexander Thom, Crieff; and Dr. Andrew C. Buist, Dunblane.

Sheriffdom of the Lothians and Peebles.—Dr. John Shaw M'Laren, Dr. David Wallace, Dr. J. C. Dunlop, and Dr. Alexander Miles, all of Edinburgh; Dr. Alexander Ballantyne, Eskbank, Midlothian; Dr. Thomas Malcolm Murray Lyon, Mid Calder; Dr. John George Wallace-James, Haddington; and Dr. John Connel, Peebles.

Sheriffdom of Stirling, Dumbarton, and Clackmannan.—Dr. D. McFadyen, Stirling; Dr. Alexander D. Fraser and Dr. Robert D. Clarkson, Falkirk; Dr. W. A. McLachlan, Dumbarton; Dr. P. Napier Grant, Lenzie; Dr. Robert Wilson, Alloa; and Dr. John Barlow and Dr. Samuel Macfarlane Sloan, Glasgow.

Sheriffdom of Roxburgh, Berwick, and Selkirk.—Dr. William Jeffrey, Jedburgh; Dr. W. Turnbull Barrie, Hawick; Dr. John McWatt, Duns; and Dr. Charles Reid, Selkirk.

Sheriffdom of Aberdeen, Kincardine, and Banff.—Dr. Alexander Ogston and Dr. J. C. Ogilvie Will, Aberdeen; Dr. John Barclay, Banff; and Dr. James Taylor, Keith.

Sheriffdom of Ross, Cromarty, and Sutherland.—Dr. William Bruce, Dingwall; Mr. Murdoch Mackenzie, Stornoway; and Dr. James Bertie Simpson, Golspie.

Sheriffdom of Dumfries and Galloway.—Dr. Thomas Ferguson, Dumfries; Dr. W. S. Spence Reid, Kirkcudbright; and Dr. D. Duke Monro, Stranraer.

Sheriffdom of Forfar.—Dr. David MacEwan and Dr. Patrick R. Murison, Dundee; Dr. A. S. McLagan Wedderburn, Forfar; and Dr. James Alexander Dewar, Arbroath.

Sheriffdom of Caithness, Orkney, and Shetland.—Dr. Samuel Elliot, Wick; Dr. Alexander Asher, Thurso; Mr. Benjamin Bell, Kirkwall; and Dr. John F. Robertson, Lerwick.

Sheriffdom of Renfrew and Bute.—Dr. J. N. Marshall, Rothesay; Dr. Donald Fraser and Dr. Thomas Graham, Paisley; Dr. James Whiteford and Dr. Thomas Philip, Greenock; Mr. R. H. Parry and Dr. A. E. Maylard, Glasgow; and Dr. Robert Allan, Ardrossan.

Sheriffdom of Ayr.—Dr. George McKerrow and Dr. James Ross Watt, Ayr; Dr. William Macfarlane, Maybole; Dr. William McAlister and Dr. William Frew, Kilmarnock; and Dr. Robert Allan, Ardrossan.

Sheriffdom of Fife and Kinross.—Dr. C. E. Douglas, Cupar; Mr. Robert Balfour Graham, Leven; Dr. J. Sutherland Mackay and Dr. H. W. Laing, Kirkcaldy; Dr. C. A. Sturrock, Dunfermline; and Mr. James Mungle, Kinross.

Sheriffdom of Inverness, Elgin, and Nairn.—Dr. John Munro Moir, Inverness; Dr. Alexander Cameron Miller, Fort William; Dr. John Dewar, Portree, Skye; Dr. Francis William Grant, Elgin; and Dr. Hugh William Mann, Larkfield, Nairn.

METROPOLITAN MEDICAL SCHOOLS.

PRIZES FOR 1897-98.

THE following is a list of prizes, &c., awarded for the session 1897-98:—

St. Bartholomew's Hospital.—Lawrence Scholarship and Gold Medal: T. J. Horder. Brackenbury Medical Scholarship: C. Riviere. Brackenbury Surgical Scholarship: H. Munday. Matthews Duncan Medal and Prize: J. L. Maxwell. Senior Scholarship in Anatomy, Physiology, and Chemistry: R. C. Elmslie. Open scholarships in Science, Chemistry, and Physics: C. E. West. Biology and Physiology: W. M. Fletcher; junior, H. R. Kidner and E. C. Williams, equal. Preliminary Scientific Exhibition: E. G. Pringle. Jeaffreson Exhibition: L. R. Tosswill. Kirkes Scholarship and Gold Medal: R. Hatfield. Bentley Prize (surgical) not awarded. Hichens Prize: F. Gröne. Wix Prize: W. E. L. Davies. Harvey Prize: (1) S. G. Mostyn; (2) R. C. Elmslie, (3) F. Gröne, and (4) E. Ladell. Sir George Burrows Prize: No award. Skynner Prize: No award. Practical Anatomy (senior): Foster Prize: R. C. Elmslie and H. Love (equal), (3) F. N. White, (4) R. T. Worthington, (5) A. E. Thomas, (6) W. R. Read, (7) E. W. J. Ladell, (8) E. L. Martin, and (9) H. J. Slade. Practical Anatomy (junior)—Treasurer's Prize: (1) T. C. Neville, (2) E. B. Smith, (3) T. P. Baldwin, (4) J. Corbin, (5) N. E. Waterfield, (6) E. C. Williams (7) T. R. Couldrey, and (8) A. S. Petrie. Shuter Scholarship: F. C. Shrubsall. Junior Scholarships: (1) E. C. Williams and (2) E. B. Smith. Junior Scholarship in Chemistry and Histology (1897): (1) R. C. Elmslie and (2) F. N. White.

Guy's Hospital.—Open Scholarships in Arts: Percy Reginald Bolus, Bancroft School, Woodford Wells, £100; Gayton Warwick Smith, Liverpool College, Certificate. Dental Students: Percival Pasley Cole, Weymouth College, £30. Open Scholarship in Science: Albert Ernest Hardman Pakes, Guy's Hospital, £150. Scholarship for University Students: Aubrey Hugh Davies, Caius College, Cambridge, £50; Reginald Cuthbert Mullins, Keble College, Oxford, Certificate; James Alison Glover, St. John's College, Cambridge, Certificate. Second Year's Prize: (1897) James Alfred Butler, £25. Junior Proficiency Prizes: Louis Edward Stamm, £20; William Henry Bowen, Claude Tessier, equal, £12 10*s.* each; Henry Crewe Keates, Certificate; George Thomas Collins, Certificate. The Michael Harris Prize for Anatomy: Claude Tessier, prize £10. William Henry Bowen, Certificate. The Sands Cox Scholarship in Physiology: Louis Edward Stamm, £15; Myer Coplans, Certificate. The Hilton Prize for Dissection: (1897) Frederick Goulburn Gibson, prize £5. The Arthur Durham Prizes for Dissections—First year's students: Richard Willan, prize £5; Carrick Hey Robertson, Certificate; William Edward James Tuohy, Certificate. Second year's Students: Hugh Davies-Colley, Claude Tessier, equal, £7 10*s.* each; Herbert William Brown, Certificate; Henry Francis Hatfield, Louis Edward Stamm, equal, Certificates. Dental Prizes—Second Year's Students: (1897) Hubert Arnold George Butler, prize, £15; Alfred William Walker, certificate; Victor George Smith, certificate; Bertram James Sumerling, certificate. First Year's Students: (1897) Percival Sidney Campkin, prize, £10; Harry Hudson Evans, certificate; (1898) Frank Warlow, prize, £10; Hugh Titford Campkin, certificate. Practical Dentistry Prize: (1897) Henry Albert Ellis Canning, prize, £10; Alfred William Walker, certificate; (1898) Percival Sidney Campkin, prize, £10; John Stewart Farnfield and Stephen Holloway Olver, equal certificates. Fourth Year's Prizes: (1897) Philip Turner, prize, £25; Harold Wilson Bruce and William Tayler Milton, equal, £5 each; Charles Leopold Granville Chapman and George Ernest Richmond, equal certificates. The Richard Bredin Prize for Clinical Study: (1897) Robert Pugh Rowlands, £25; (1898) William Tayler Milton, £25. The Golding-Bird Gold Medal and Scholarship for Sanitary Science: Robert Wynne Charles Pierce, £20. The Treasurer's Gold Medal for Clinical Medicine: (1897) Robert Pugh Rowlands; (1898) William Tayler Milton. The Treasurer's Gold Medal for Clinical Surgery: (1897) Robert Howard; (1898) Frederick Edward Walker and Philip Turner.

King's College, London.—Faculty of Medicine, 1897-98.—Recommended for the Associateship: R. M. Cowie, H. Dingle, L. H. Fuller, F. H. Jacob, J. E. London, and R. P. Williams. Scholarships and Exhibitions.—Senior Scholarship: C. A. Sprawson and A. Brown (equal). Second Year Scholarship: A. Edmunds. Junior Scholarship: E. A. Bell. Warneford Scholarship (resident): J. C. Briscoe. Warneford Scholarship (Class I.): H. B. Day and A. A. Myers. Sambrooke Scholarship: M. R. C. MacWatters and J. A. Drake (equal). Rabbeth Scholarship: A. A. Myers and H. B. Day (equal). Special Prizes.—Leathes: W. H. Lowman; Warneford (first): W. H. Lowman; Warneford (second): J. M. Twentyman; Barry (Divinity): A. A. Myers; Tanner: C. A. Sprawson. Todd (Medical Clinical): C. A. Sprawson. General Prizes and Certificates—Winter session, 1897-98, summer session 1898.—Divinity: E. A. Bell; Anatomy: W. L. Stuart; Materia Medica: W. W. Campbell; Hygiene: C. A. Sprawson; Pathological Anatomy: C. A. Sprawson; Obstetric Medicine: W. H. Lowman; Forensic Medicine: W. H. Lowman; Clinical Surgery: R. R. Mowll; Clinical Surgery (Professor Rose's prize): I. M. Jefferiss.

University College, London.—Winter Session, 1897-98.—Entrance Exhibitions.—L. A. E. de Zilwa (£137 11*s.*); C. S. Parker and R. E. Lloyd (£57 15*s.* each). Atchison Scholarship (£55 per annum for two years): J. E. Simpson. Bruce Medal: J. E. Simpson. Physiology—Senior Class: Gold medal, R. E. Lloyd; silver medal, L. A. E. de Zilwa; certificates, (3*) L. G. Hopkins and (4*) W. S. Rooke. Second Class: F. J. A. Mayes, C. S. Parker, and S. H. Bown. Third Class: C. A. Hewavitarna, G. W. Curtis, and F. J. Lawson. Junior Class: Silver Medal, J. E. Stratton; certificate, (2*) R. H. Aders. Second Class: G. F. I. Harkness, C. J. Loosely, and H. A. Lyth. Third Class: J. B. Burt, A. F. Horn, and G. B. McKean. Anatomy—Senior Class: Gold Medal, C. S. Parker; Silver Medal, S. H. Bown. Second Class: S. Bree and E. S. Littlejohn. Third Class: W. T. Crawford, L. A. E. de Zilwa, and R. E. Lloyd. Junior Class: Silver Medal, H. A. Lyth; certificate, (2*) A. F. Horn. Second Class: G. B. McKean and J. E. Stratton. Third Class: J. A. Smyth, J. B. Burt, and G. F. I. Harkness. Medicine: Gold Medal, W. L. Griffiths; first silver, J. E. Phillips; second silver, Ivor L. Tuckett; certificates, (4*) A. Ricketts and J. E. Simpson (equal), (6*) H. M. Hart-Smith. Surgery: Gold Medal, J. E. Simpson. Second Class: W. L. Griffiths, H. M. Hart-Smith, and Ivor L. Tuckett. Third Class: J. E. Phillips. Pathology—Morbid Histology and Bacteriology—Tuke Silver Medal: G. E. Charles. Tuke Bronze Medal: A. R. G. Pocock. Third Class: A. R. Spencer. Practical Surgery—Erichsen Prize: W. L.

Digitized by Google

Griffiths. Certificates: (2*) D. Davies and H. M. Hart-Smith, equal; (4*) J. E. Simpson. Second Class: Ivor L. Tuckett. Clinical Medicine—Senior Class—Fellowes Gold Medal: H. M. Hart-Smith. Fellowes Silver Medal: Ivor L. Tuckett. Certificates: (3*) W. L. Griffiths, J. E. Phillips, A. Ricketts, and J. E. Simpson (equal). Second Class: D. S. Baker. Junior Class—Fellowes Silver Medal: P. M. Heath. Certificates: (2*) W. F. Addey, (3*) A. R. G. Pocock, B. E. Reynolds, and W. L. Steele (equal). Second Class: W. Bastian, T. Evans, A. L. Murison, and E. W. D. Swift. Third Class: H. S. Capper and A. R. Spencer. Clinical Dental Surgery—Silver Medal: J. E. Simpson. Certificates: (2*) W. L. Griffiths, (3*) J. E. Phillips, and (4*) Ivor L. Tuckett. Summer Session, 1897-98—Histology and Practical Histology—Second Class: J. B. Burt, G. F. I. Harkness, C. A. Hewavitarna, H. A. Lyth, and J. E. Stratton. Third Class: R. H. Aders, C. H. Berry, and G. A. Bosson. Chemistry—Practical Class (Int. Med.)—Prize: W. T. Crawford. Second Class: S. M. Banham, G. E. Waugh, and C. S. Parker. Chemistry and Chemical Physics (Conjoint Board)—Prize: V. K. Sadler. Third Class: E. C. E. Barnes and W. H. Neil. Practical Chemistry (Conjoint Board)—Prize: V. K. Sadler. Certificate: (2*) W. H. Neil. Third Class: O. Marshall. Materia Medica and Therapeutics—Gold medal: L. A. E. de Zilwa. Certificate: (2*) C. S. Parker. Second Class: S. H. Bown. Third Class: D. Roberts. Midwifery—Junior Class—Silver Medal: P. M. Heath. Certificate: (2*) W. E. Peck. Second Class: C. J. I. Krumbholz and E. W. D. Swift. Third Class: A. R. G. Pocock. Medical Jurisprudence.—Gold Medal: A. R. G. Pocock. Pathology—Filliter exhibition of £30: H. S. Capper. Silver Medal: E. W. D. Swift. Second Class: A. R. G. Pocock and A. R. Spencer. Third Class: M. T. Male. Ophthalmic Medicine and Surgery—Third Class: J. E. Simpson. Clinical Medicine—Junior Class: Fellowes Silver Medal—N. F. Stallard. Certificates: (2*) M. T. Male and C. Visger (equal). Second Class: P. T. H. Steadman, H. Stuart, and C. W. Wirgman.

* Obtained the number of marks qualifying for a prize.

St. George's Hospital.—Brackenbury Prize in Medicine: B. Percival. Brackenbury Prize in Surgery: H. S. Barwell. Webb Prize in Bacteriology: H. Spitta. Treasurer's Prize: R. B. Ainsworth. Sir Benjamin Brodie's Clinical Prize in Surgery: R. B. Ainsworth. The Henry Charles Johnson Prize in Anatomy: J. C. S. Rashleigh. Honorary Certificates in Anatomy: Keppel H. Reed, S. H. Nathan, Adrian Caddy, and C. M. N. May. Sir Charles Clarke's Prize: H. G. Drake-Brockman.

St. Thomas's Hospital.—Winter Session, 1897-98.—Entrance Science Scholarships: W. H. Harwood-Yarred, first scholarship, £150, and certificate of honour; and F. H. Whitehead, scholarship, £60, and certificate of honour. University Scholarship: F. C. Eve, scholarship, £50, and certificate of honour. First Year's Students: W. H. Harwood-Yarred, the William Tite Scholarship, £27 10*s.*, and certificate of honour; J. E. Adams, college prize, £20, and certificate of honour; O. Mills, college prize, £10, and certificate of honour; and C. U. Ind, certificate of honour. Second Year's Students: C. N. Sears, the Peacock Scholarship, £38 10*s.*, and certificate of honour; A. F. Miskin, college prize, £20, and certificate of honour; and A. B. Lindsey, college prize, £10, and certificate of honour. Practical Medicine: E. F. Buzzard, the Mead Medal, founded by Mr. and Mrs. Newman Smith. Surgery and Surgical Anatomy: S. O. Bingham, the Cheselden Medal, founded by the late Mr. George Vaughan; S. A. Lucas, certificate of honour; and H. D. Singer, certificate of honour. Pathology and Morbid Anatomy: A. W. Sikes, the Bristowe Medal. Grainger Testimonial Prize: R. Beer, prize, £15; E. M. Corner, certificate of honour. For Reports of Surgical Cases: C. W. Pilcher, the Solly Medal and prize. For General Proficiency and Good Conduct: H. E. Hewitt, the treasurer's gold medal.

St. Mary's Hospital.—1897—Entrance Scholarship in Natural Science of £144: M. F. Kelly. 1897—Entrance Scholarship in Natural Science of £78 15*s.*: J. B. Albury. 1897—Entrance Scholarship in Natural Science of £78 15*s.*: D. E. Finlay. 1897—Entrance Scholarship in Natural Science of £52 10*s.*: J. H. Wells. 1897—University Scholarship of £57 15*s.*: C. Killick, B.A. 1897—University Exhibition of £39 7*s.* 6*d.*: A. Whitmore, B.A. 1897—University Exhibition of £39 7*s.* 6*d.*: E. R. Clarke, B.A. 1897—Meadows Memorial Prize: J. B. Page. 1898—Kerslake Scholarship of value of £25: C. W. Buckley. Summer session, 1897.—Third year—Practical Surgery: J. A. H. Brincker, B.A., and E. R. Hunt, B.A. Second year—Midwifery: J. B. Page, F. C. Lewis, and A. F. MacCallan, B.A. Medical Jurisprudence: T. W. Bates, M.A., A. E. Horn, J. A. H. Brincker, B.A., and R. C. Leaning. First year—Materia Medica: W. H. Willcox, B.Sc., E. W. Holyoak, and V. C. Bensley. Practical Chemistry: H. T. Doble, H. M. Major, and F. C. Lambert. Chemistry: H. T. Doble, G. J. Evans, and R. Butterworth. Prizes in Ophthalmology of £10 10*s.*: A. S. Gardiner and G. S. Keeling. Prizes in Dermatology of £5 5*s.*: J. B. Page and V. C. Bensley. Prize in Psychological Medicine of £3 3*s.*: T. W. Bates, M.A. Clinical Surgery Prize, 1897—98: J. A. H. Brincker, B.A., and E. R. Hunt, B.A. Clinical Medicine Prize, 1897—98: J. A. H. Brincker, B.A., and J. B. Page. Clinical Medicine Prize, 1898-99: W. H. Willcox, B.Sc., and W. B. Watson. Winter Session, 1897-98.—Third year.—Medicine: C. W. Buckley and F. S. Dawe, B.Sc. Surgery: A. G. Wilson, B.A., and C. W. Buckley. Practical Surgery: F. W. Sumner, B.A., and C. W. Buckley. Pathology: H. Agate and J. A. H. Brincker, B.A. Second year—Anatomy: T. M. Harris, B.A., D. W. Bishop, and C. C. C. Shaw. Physiology: C. C. C. Shaw. Histology: W. J. Morrish, D. W. Bishop, and C. C. C. Shaw. First year—Anatomy: M. F. Kelly, V. Nesfield, and D. E. Finlay. Physiology: M. F. Kelly and H. E. Corbin, B.Sc. Biology: N. Low, G. Y. Evans, O. Jevers, and G. E. Wood. Special Prize, 1897.—In Anatomy and Physiology (including Histology): W. H. Willcox, B.Sc.; Prosectors, D. W. Bishop and J. Gay-French.

The London Hospital.—Session, 1897-98.—Price Scholarship in Science (£120): J. Jones. Price Scholarship in Anatomy and Physiology (£60): R. Warren. Entrance Science Scholarships—£60 Scholarship, R. V. Dolbey; £35 Scholarship, M. T. Williams. Buxton Scholarships.—Arts: £30 Scholarship, M. Culpin; £20 Scholarship, G. Rodolph. Clinical Medicine: £20 Scholarship, A. F. Tredgold. Clinical Surgery: £20 Scholarship (equal, scholarship divided), R. Howard and G. R. Slade. Clinical Obstetrics: £20 scholarship, J. Sherren. Duckworth Nelson Prize: biennial, £10, awarded 1897. Second Prize: A. G. Payne and H. G. Williams. Dental Surgery—First Prize: W. H. Thomas. Second Prize: H. H. Belsey.

THE PRINCE OF WALES'S HOSPITAL FUND.

LAST year two stamps were issued on behalf of this fund. They produced a sum of about £35,000, and were issued to give small subscribers a handy and convenient form of receipt, which has become popular. This year a new issue for 1898 is made. It consists of four stamps, each of distinct design, with a face value of 1*s.*, 2*s.* 6*d.*, 5*s.*, and 10*s.* respectively. The designs for the stamps and the colours in which they are printed were selected by H.R.H. the Prince of Wales. The 1*s.* stamp is printed in red, the 2*s.* 6*d.* stamp in blue, the 5*s.* stamp in dark green, and the 10*s.* stamp in a lighter green. Each contains a vignette of the figure of Charity, with the words "Prince of Wales's Hospital Fund"

The five-shilling stamp reproduced in black-and-white and enlarged by one-third, to show the details.

and the date 1898 in the top right-hand corner. A facsimile of the Prince's signature appears at the bottom. The 1*s.*, 5*s.*, and 10*s.* stamps have the Prince of Wales's feathers introduced, whereas in the 2*s.* 6*d.* stamp these are replaced by a fleur-de-lis. The 10*s.* stamp is intended as a national emblem, the vignette being enclosed by an ornamental border containing the rose, shamrock, thistle, and leek. Our illustration shows the 5*s.* stamp.

HOSPITAL REFORM IN IRELAND.

MR. T. GARRETT HORDER, the Secretary of the Hospital Reform Association, has sent us some statistics of the various hospitals in Ireland. In 1896 the population of Ireland was 4,486,100. The number of hospitals, including county infirmaries, is 92. Of this number the Dublin registration area with a population in 1891 of 349,594 has 31 hospitals. The proportion of hospitals to population is thus seen to be enormous. Some statistics follow with reference to various items in hospital management and income as regards Dublin.

THE DUBLIN HOSPITALS.

Number of hospitals in Dublin registration area... ...	31
Number of beds	2,438
Population of registration area (1891)	349,594
Number of patients admitted in 1897	22,572
Number of out- or dispensary-patients (attendances) ...	149,766
Number of maternity patients (extern)	5,125

The following hospitals are supported almost entirely by Government grants:—

		Government grant.
House of Industry hospitals.	The Hardwicke Fever Hospital	£7472
	The Richmond Surgical Hospital	
	The Whitworth Medical Hospital	
	The Lock Hospital (females)	2000

The following are supported by Government grants, by assessments either on the county of Dublin or on the city of Dublin, by subscriptions and donations, by payments from patients, and by the Hospital Sunday Fund:—

	Hospital Sunday Fund	Government grant.	Subscriptions and donations.	Assessments.	Patients' payments.
	£	£	£	£	£
Steevens' Hospital ...	126	1,300	431	200	1,109
Meath Hospital	447	600	1,985	1,300	224
Cork-street Fever Hospital	186	2,500	668	360	3,544
Rotunda Lying-in Hospital	299	700	1,058	250	417
Coombe Lying-in Hospital	101 (1896)	500	325	200	24
Hospital for Incurables	—	250	1,055	350	—
St. Mark's Eye and Ear Hospital	107 (1896)	100	208	150	579

The following other hospitals receive grants from the Corporation of Dublin.

	Amount (1896).		Amount (1896.)
Sir Patrick Dun's Hospital	£450	National Children's Hospital	£125
City of Dublin Hospital ...	300	The Orthopædic Hospital ...	125
Mercer's Hospital...	300	National Maternity Hospital	?
The Children's Hospital ...	?	St. Vincent's Hospital ...	?
Jervis-street Hospital... ...	?		
Mater Misericordiæ Hospital	500		

Cork with a population of 75,345 has 12 hospitals with 629 beds, 3671 in-patients, 40,827 out-patients, and 383 maternity patients. Belfast with a population of 255,950 has 12 hospitals with 514 beds, 4466 in-patients, and 50,594 out-patients. County infirmaries number 32 with 1588 beds, 11,395 in-patients, and 24,963 out-patients. In all, these institutions possess 75 nurses and 22 probationers. The discrepancy between the relation of hospitals to population existing in Cork as compared with Belfast will strike the reader at once and it is obvious that some readjustment is urgently required.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelsea Sanitary District.—Dr. Louis Parkes has turned his attention to the recent manifestations of scarlet fever and of diphtheria in the eight parishes constituting western London, and he furnishes in his annual report for 1897 two tables and some charts based upon the notifications of each of these diseases for 1890 to 1897. In dealing with Chelsea the district of Kensal Town has been very properly omitted as its topographical relations to Chelsea proper are obviously but remote. The lessons which Dr. Parkes draws from the tables are (1) that in the case of diphtheria fluctuations in its prevalence are much less marked than is the case with scarlet fever; (2) that the prevalence or absence of diphtheria is a much more local circumstance than is the prevalence or absence of scarlet fever, a disease which apparently possesses a greater diffusive power than does diphtheria. For instance, in dealing with diphtheria it is common to find it highly prevalent in one parish and but little prevalent in adjoining parishes, whereas scarlet fever has a greater tendency to diffuse itself over wider areas; the infection, however, of diphtheria is much more persistent in an invaded area than is that of scarlet fever. Dr. Parkes does not regard the future *quâ* diphtheria prevalence as discouraging, for the figures would seem to indicate that the wave of diphtheria prevalence which has passed over London since 1892 is now on the decline. As Dr. Parkes observes, the precise factors which may favour the persistence of diphtheria are but very imperfectly understood and it may be that social circumstances such as overcrowding and poverty are at least as potent for harm as are purely insanitary conditions; in other words, the extent of the prevalence of diphtheria is largely governed by opportunities for infection. Assuming, however, the diphtheria wave to be on the decline in London, what we have to do is to render both the social and sanitary condition of the population such that a wave of equal virulence will when it comes reap a smaller harvest.

Plymouth Urban District.—In advocating the erection of swimming baths Mr. F. M. Williams points out how very important it is in a place like Plymouth where there is a large seafaring population that every facility for learning to swim should be afforded. It seems that in the elementary schools of Plymouth only eight of the boys are able to swim. The number of articles disinfected during 1897 affords a capital illustration of the amount of labour which the arrival of an infected vessel necessitates. Many of our readers will remember the circumstances connected with the s.s. *Nubia*, which brought cases of cholera to Plymouth in January of last year, and they will read with interest that of 31,000 articles disinfected during 1897 no less than 27,000 came from the infected vessel. In dealing with the prevalence of disease, Mr. Williams deplores the extension of syphilis amongst the military, naval, and civil populations of our great centres, and in commenting thus he has doubtless in mind circumstances with which he is familiar in a garrison town like Plymouth. The repeal of the Contagious Diseases Act has, Mr. Williams states, been most disastrous as regards the moral and physical well-being of the young in great naval and military centres. It is certainly well that the medical officer of health should regard this question as distinctly a branch of preventive medicine. Whilst dealing with the subject of cattle inspection and milk-supply attention is called to the necessity for the inspection by a veterinary surgeon of all milch cows yielding milk for the people of Plymouth, and as a step in the right direction Mr. Williams has apparently prevailed upon the principal dairy company to set up a filtering and sterilising plant.

Brighton Urban District.—The population of Brighton in 1897 was estimated at 121,401, and for the year in question the general death-rate was but 15·3 per 1000—the lowest yet recorded for Brighton. Under the heading of small-pox Dr. Newsholme furnishes a series of diagrams illustrating very clearly the altered age incidence of fatal small-pox side by side with the extension or diminution of the practice of vaccination. With the decrease of vaccination which has taken place within recent years we see a tendency for small-pox to revert to its pre-vaccination incidence on the infantile population, and we much fear that the next decade will witness a marked accentuation of this tendency. As regards enteric fever, Dr. Newsholme reports that detailed investigation was made into the circumstances connected with the 88 cases which originated in Brighton during 1897, and it appeared from the evidence procurable that in 47 cases no shellfish had been eaten within three weeks of attack; in 11 cases there was doubt as to the point, and in 27 cases shellfish derived from a sewage-contaminated source had been consumed at a time consistent with their having been the cause of the attack. In the 3 remaining cases the patients were intimately connected with the sale or storage of shellfish. It would seem, therefore from this that some 27 or 30 cases of enteric fever may have derived their infection from specifically contaminated shellfish; indeed, from the details with regard to certain illustrative cases, a thesis of this nature would appear to be the best and most reasonable explanation. Unfortunately we cannot well ascertain the incidence of enteric fever on the shellfish-eating community as compared with that upon the non-shellfish-eating community, and in all questions of this nature the decision must be arrived at by building up the best chain of evidence possible from the links available. It is to be deplored that ere this we have not had legislation in reference to this question of shellfish culture and disease, and it is to be hoped that Mr. Chaplin may early next session be able to introduce his long-expected and much-needed measure. Dr. Newsholme gives an interesting account of the means taken in Brighton to control the spread of measles, and he expresses the opinion that notification of this disease would only be successful if dual notification were rigidly enforced, and if only the first case in a household outbreak should require to be notified by the medical practitioner. He would, however, have the parent notify every case.

Blackpool Urban District.—There were but 50 cases of enteric fever notified in Blackpool during 1897 as against 66 in the previous year, but as there were 15 deaths in 1897 and only 13 in 1896 Dr. Jasper Anderson regards it as probable that a number of slight cases are not reported. We expect this is a very common feature in every town, but it may obviously obtain in some years more than in others according as to whether the type of the disease is well or ill developed. One death from typhus fever—infection introduced from Liverpool—occurred in Blackpool during 1897.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6583 births and 4988 deaths were registered during the week ending August 27th. The annual rate of mortality in these towns, which had increased in the six preceding weeks from 14·7 to 22·0 per 1000, further rose to 23·2. In London the rate was 21·5 per 1000, while it averaged 24·3 in the thirty-two provincial towns. The lowest death-rates in these towns were 13·7 in Huddersfield, 16·5 in Oldham, 16·8 in Nottingham, and 16·9 in Swansea; the highest rates were 30·9 in Liverpool, 32·3 in Preston, 35·2 in Sunderland, and 38·5 in Wolverhampton. The 4988 deaths in these towns included 1541 which were referred to the principal zymotic diseases, against 1127 and 1250 in the two preceding weeks; of these, 1321 resulted from diarrhœa, 84 from whooping-cough, 53 from measles, 45 from diphtheria, 19 from "fever" (principally enteric), and 19 from scarlet fever. The lowest death-rates from these diseases were recorded in Swansea, Oldham, Burnley, Huddersfield, and Halifax; and the highest rates in Wolverhampton, Salford, Preston, and Sheffield. The greatest mortality from measles occurred in Wolverhampton and Norwich; from whooping-cough in Sheffield, Sunderland, and Swansea: and from diarrhœa in Liverpool, Birkenhead, Leicester, Salford, Wolverhampton, Preston, and Sheffield. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 45 deaths from diphtheria included 21 in London, 4 in Liverpool, and 3 in West Ham. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and only 2 small-pox patients were under treatment in the Metropolitan Asylum Hospitals on Saturday, August 27th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of

Digitized by Google

the week was 2178, against 2326, 2293, and 2241 on the three preceding Saturdays; 182 new cases were admitted during the week, against 224, 201, and 187 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 171 and 196 in the two preceding weeks, declined again to 135, and were 24 below the corrected average. The causes of 54, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Nottingham, Oldham, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Bristol, Leicester, Liverpool, and Preston.

In thirty-three of the largest English towns 6749 births and 5242 deaths were registered during the week ending Sept. 3rd. The annual rate of mortality in these towns, which had increased in the seven preceding weeks from 14·7 to 23·2 per 1000, further rose last week to 24·4. In London the rate was 22·0 per 1000, while it averaged 26·0 in the thirty-two provincial towns. The lowest death-rates in these towns were 15·1 in Halifax, 15·3 in Huddersfield, 17·2 in Oldham, and 17·3 in Portsmouth; the highest rates were 31·1 in Bolton, 31·2 in Gateshead, 36·7 in Wolverhampton and in Salford, and 37·0 in Sunderland. The 5242 deaths in these towns included 1646 which were referred to the principal zymotic diseases, against 1250 and 1541 in the two preceding weeks; of these, 1438 resulted from diarrhœa, 75 from whooping-cough, 43 from diphtheria, 40 from "fever" (principally enteric), 30 from measles, 19 from scarlet fever, and 1 from small-pox. The lowest death-rates from these diseases were recorded in Plymouth, Oldham, Huddersfield, and Halifax; and the highest rates in Wolverhampton, Salford, Bolton, Preston, and Sunderland. The greatest mortality from whooping-cough occurred in Croydon, Halifax, and Sunderland; and from diarrhœa in Wolverhampton, Leicester, Salford, Bolton, Preston, Sheffield, Hull, and Sunderland. The mortality from measles, from scarlet fever, and from "fever" showed no marked excess in any of the large towns. The 43 deaths from diphtheria included 19 in London, 5 in Swansea, 4 in Leeds, 3 in Birkenhead, and 3 in Liverpool. One fatal case of small-pox was registered in Gateshead, but not one in London or in any other of the thirty-three large towns; and only 2 small-pox patients were under treatment in the Metropolitan Asylum Hospitals on Saturday last, Sept. 3rd. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2240, against 2293, 2241, and 2178 on the three preceding Saturdays; 238 new cases were admitted during the week, against 201, 187, and 182 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 196 and 135 in the two preceding weeks, further declined to 127 last week, and were 16 below the corrected average. The causes of 44, or 0·8 per cent. of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bradford, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Huddersfield, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 18·1 per 1000 in the two preceding weeks, rose again to 18·4 during the week ending August 27th, but was 4·8 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·9 in Perth and 13·0 in Leith to 26·4 in Greenock and 28·9 in Paisley. The 556 deaths in these towns included 89 which were referred to diarrhœa, 27 to whooping-cough, 9 to "fever," 8 to measles, 5 to scarlet fever, and 2 to diphtheria. In all, 140 deaths resulted from these principal zymotic diseases, against 136 and 118 in the two preceding weeks. These 140 deaths were equal to an annual rate of 4·6 per 1000, which was 2·6 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 80 and 70 in the two preceding weeks, rose again to 89 last week, and included 44 in Glasgow, 11 in Paisley, 9 in Edinburgh, and 9 in Dundee. The 27 deaths from whooping-cough showed a slight further increase upon recent weekly numbers, and included 8 in Glasgow and 8 in Aberdeen. The deaths referred to different forms of "fever," which had increased from 1 to 9 in the three preceding weeks, were again 9 last week, of which 8 occurred in Glasgow. The 8 fatal cases of measles exceeded by 2 the number registered in the preceding week, and included 3 in Glasgow, where 2 of the 5 deaths from scarlet fever were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 71 and 80 in the two preceding weeks, declined again to 64, and were 14 below the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths in these eight towns were not certified.

The annual rate of mortality in the eight Scotch towns, which had been 18·1 and 18·4 per 1000 in the two preceding weeks, further rose to 19·8 during the week ending Sept. 3rd, but was 4·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Perth, and 17·4 in Aberdeen to 27·9 in Leith and 28·9 in Greenock. The 596 deaths in these towns included 81 which were referred to diarrhœa, 22 to whooping-cough, 9 to "fever," 5 to measles, 5 to scarlet fever, and 2 to diphtheria. In all, 124 deaths resulted from these principal zymotic diseases against 118 and 140 in the two preceding weeks. These 124 deaths were equal to an annual rate of 4·1 per 1000, which was 3·5 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 70 and 89 in the two preceding weeks, declined to 81 last week, of which 39 occurred in Glasgow, 12 in Edinburgh, 9 in Leith, and 7 in Greenock. The 22 deaths from whooping-cough showed a decline of 5 from the number in the preceding week, and included 13 in Glasgow and 5 in Aberdeen. The deaths referred to different forms of "fever," which had been 9 in each of the two preceding weeks, were again 9 last week, of which 5 occurred in Glasgow and 2 in Paisley. The 5 fatal cases of scarlet fever also corresponded with the number recorded in the preceding week, and included 3 in Edinburgh and 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 80 and 64 in the two preceding weeks, rose again to 72 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 34, or nearly 6 per cent. of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·5 and 21·8 per 1000 in the two preceding weeks, rose again to 22·4 during the week ending August 27th. During the four weeks ending on that date the death-rate in the city averaged 23·4 per 1000, the rate during the same period being 21·0 in London and 17·1 in Edinburgh. The 150 deaths registered in Dublin during the week under notice showed a slight increase upon the number in the previous week, and included 29 which were referred to the principal zymotic diseases, against 31 and 28 in the two preceding weeks; of these, 24 resulted from diarrhœa, 3 from "fever," 2 from diphtheria, but not one either from small-pox, measles, scarlet fever, or whooping-cough. These 29 deaths were equal to an annual rate of 4·3 per 1000, the zymotic death-rate during the same period being 6·4 in London and 2·5 in Edinburgh. The fatal cases of diarrhœa, which had increased from 4 to 22 in the five preceding weeks, further rose to 24. The deaths referred to different forms of "fever," which had been 3 in each of the two preceding weeks were again 3 during the week under notice. The 2 fatal cases of diphtheria exceeded the number recorded in any recent week. The 150 deaths in Dublin included 51 of infants under one year of age, and 29 of persons aged upwards of sixty years; the deaths of infants showed a slight further increase upon recent weekly numbers, while those of elderly persons showed a decline. Four inquest cases and 4 deaths from violence were registered, and 51, or rather more than a third, of the deaths occurred in public institutions. The causes of 10, or nearly seven per cent. of the deaths in the city were not certified.

The death-rate in Dublin, which had been 21·8 and 22·4 per 1000 in the two preceding weeks, further rose to 27·6 during the week ending Sept. 3rd. During the four weeks ending on Saturday last the rate of mortality in the city averaged 24·3 per 1000, the rate during the same period being 21·9 in London and 17·1 in Edinburgh. The 185 deaths registered in Dublin during the week under notice showed an

Digitized by Google

increase of 35 upon the number in the preceding week, and included 39 which were referred to the principal zymotic diseases, against 28 and 29 in the two preceding weeks; of these, 33 resulted from diarrhœa, 4 from whooping-cough, 1 from measles, 1 from "fever," but not one either from small-pox, scarlet-fever, or diphtheria. These 39 deaths were equal to an annual rate of 5·8 per 1000, the zymotic death-rate during the same period being 5·9 in London and 3·2 in Edinburgh. The fatal cases of diarrhœa, which had increased in the five preceding weeks from 9 to 24, further rose to 33 last week. The 4 deaths referred to whooping-cough exceeded the number recorded in any recent week, while the mortality from "fever" showed a decline. The 185 deaths in Dublin last week included 62 of infants under one year of age, and 33 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further increase upon those recorded in recent weeks. Seven inquest cases and 8 deaths from violence were registered; and 53, or more than a fourth of the deaths occurred in public institutions. The causes of 16, or nearly 9 per cent. of the deaths in the city last week were not certified.

THE SERVICES.

NEW WARRANT FOR THE INDIAN MEDICAL SERVICE.

THE following is the text of the Warrant published in the *London Gazette* of Friday, August 26th, granting new titles to the Indian Medical Service:—

India Office, August 26th, 1898.

VICTORIA, R.I.

Whereas We have deemed it expedient to alter the Ranks of the Officers of Our Indian Medical Service:

Our Will and Pleasure is that the following alterations shall be made:

Present Ranks.	New Ranks.
Surgeon-Colonel	Colonel.
Brigade-Surgeon-Lieutenant-Colonel ... ... / Surgeon-Lieutenant-Colonel	Lieutenant-Colonel.
Surgeon-Major	Major.
Surgeon-Captain	Captain.
Surgeon-Lieutenant	Lieutenant.

Officers above the rank of Surgeon-Colonel shall in future be styled Surgeon-Generals (ranking as Major-Generals), and the title of Surgeon-Major-Generals now serving shall be altered accordingly.

It is further Our Will and Pleasure that the following alterations shall be made in the honorary rank of the Senior Assistant Surgeons of the Subordinate Medical Department in India:

Present Honorary Ranks.	New Honorary Ranks.
Surgeon-Major	Major.
Surgeon-Captain	Captain.
Surgeon-Lieutenant	Lieutenant.

Given at Our Court at Osborne, this tenth day of August, one thousand eight hundred and ninety-eight, in the sixty-second year of Our reign.

By Her Majesty's Command.

GEORGE HAMILTON.

ROYAL NAVY MEDICAL SERVICE.

Staff-Surgeon Horace Ximenes Browne has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet. Staff-Surgeon Charles William Buchanan-Hamilton has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet Staff-Surgeon Arthur William May has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet. Staff-Surgeon Charles Hazlitt Upham has been allowed to withdraw from Her Majesty's Service with a gratuity.

The following appointments are notified:—Fleet-Surgeons: John Lyon to the *President;* William R. White to the *Magnificent;* and George W. Bell to the *Hannibal.* Staff-Surgeons: John Lowney to the *Proserpine;* Daniel J. P. McNabb to the *Northampton;* Hamilton Meikle to the *Pearl;* E. G. Swan to the *Collingwood;* and F. J. Burns to the *Boscawen.* Surgeons: Herbert Holyoake to the *Pembroke,* additional; Harold G. T. Major to the *Victory;* Shirley H. Birt to the *Victory;* Henry W. Finlayson to the *Vivid;* Robert S. Bernard James, W. W. Stanton, and Arthur E. Kelsey to Haslar Hospital; William Hackett to Plymouth Hospital; Joseph C. Wood to the *Britannia;* and Charles R. Sheward to the *Vivid.*

ROYAL ARMY MEDICAL CORPS.

The under-mentioned officers retire on retired pay: Colonel Charles F. Pollock and Major Arthur Harding, half-pay. Lieutenant-Colonel H. Charlesworth has assumed the duties of Recruiting and Embarking Medical Officer (Portsmouth). Major T. G. Lavie has embarked for Egypt.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Robert Stirling, M.D., 4th Volunteer Battalion the Black Watch (Royal Highlanders), to be Surgeon-Captain.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Captain W. W. Lake to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 8th Lancashire: Surgeon-Major A. R. Hopper to be Surgeon-Lieutenant-Colonel. 1st Shropshire and Staffordshire: Surgeon-Captain R. P. Mackenzie, M.B., resigns his commission. 1st Sussex: Surgeon-Lieutenant G. A. Skinner resigns his commission. *Rifle:* 9th Lanarkshire: The under-mentioned Surgeon-Lieutenants to be Surgeon-Captains: A. Campbell, M.B., and J. Bradford. 2nd Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Captain E. D. Berton, M.B., to be Surgeon-Major. 3rd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Captain F. F. Moore resigns his commission; also is granted the rank of Surgeon-Major, with permission to continue to wear the uniform of the battalion on his retirement. 2nd (Berwickshire) Volunteer Battalion the King's Scottish Borderers: Alexander John Campbell, M.B., to be Surgeon-Lieutenant.

THE ROYAL ARMY MEDICAL CORPS IN THE SOUDAN.

The following are the arrangements in detail:—

The principles and methods laid down in the regulations for the provision of hospital and medical services in the field have been followed in the late Soudan expedition, with such additions and modifications as were considered necessary to best adapt them to the climate, to the nature of the expedition, and to the work which had to be fulfilled. A medical officer accompanied every corps unit; brigades were furnished with sectional field hospitals and these were also attached to the cavalry and artillery; the wounded and sick were transported from the front by the Nile to Atbara in barges specially fitted up as temporary hospitals. The water-carriage of wounded is, it may be remarked, about the best and most comfortable transport which can be devised for the purpose. Large stationary hospitals, which are equipped with all practicable conveniences and comforts, are located at Atbara, Abadia, Wady Halfa, and Shellal. Two sets of Roentgen ray apparatus have also been provided.

The citadel hospital at Cairo is a very fine, well-placed and well-ventilated building; the weakest point about it is the conservancy accommodation; but the dry earth system is, or was, in use and is most carefully supervised and worked.

Principal Medical Officer—Surgeon-General Taylor.
Secretary—Major Wilson, C.M.G.
Principal Medical Officer of the British Division of two Brigades—Lieutenant-Colonel Macnamara.

First Brigade.

Senior Medical Officer—Lieutenant-Colonel Sloggett.
Warwickshire Regiment—Major Irwin.
Lincolnshire Regiment—Major Adamson.
Cameron Highlanders—Captain Mathias.
Seaforth Highlanders—Lieutenant Bliss.

Five sectional field hospitals of 25 beds each are attached to this brigade:—

No. 1 Sectional Field Hospital—Major Myles.
No. 2 Sectional Field Hospital—Major Webb.
No. 3 Sectional Field Hospital—Major Robinson.
No. 4 Sectional Field Hospital—Major Wardrop.
No. 5 Sectional Field Hospital—Major Dodd.

Second Brigade.

Senior Medical Officer—Lieutenant-Colonel Hughes.
1st Battalion Grenadier Guards—Major Kilkelly and Captain Austin.

Digitized by Google

Northumberland Fusiliers—Lieutenant Jephson.
Lancashire Fusiliers—Captain Luther.
Rifle Brigade—Major O'Callaghan.

Five sectional field hospitals of 25 beds each are attached to this brigade :—

No. 6 Sectional Field Hospital—Major M'Neece.
No. 7 Sectional Field Hospital—Major Wilkinson.
No. 8 Sectional Field Hospital—Major Stewart.
No. 9 Sectional Field Hospital—Major Thompson.
No. 10 Sectional Field Hospital—Major Jones.

Cavalry and Artillery.

21st Lancers—Major Pinches.
Artillery—Major Clarkson and Lieutenant Gaine.

To the Cavalry is attached :—

No. 11 Sectional Field Hospital of 25 beds—Major Sawyer.

To the Artillery :—

No. 12 Sectional Field Hospital, with 25 beds—Major Barnes.

The Convoy of the Wounded.

The wounded will be taken down the Nile on barges fitted as temporary hospitals to four stationary hospitals at Shellal, Wady Halfa, Abadia, and Atbara. Each convoy boat contains 25 beds. The medical officers in charge are :—Major Hunter, D.S.O., Captain Reily, Captain Graham, Lieutenant Huddlestone, Major Carr, Captain Thomson, Captain Peeke, Lieutenant M'Kessack.

Shellal Hospital is close to Assouan. It contains 50 beds under the charge of the following medical officers :—Captain J. Hayes and Lieutenant Hearn.

Wady Halfa Hospital also contains 50 beds under the charge of the following medical officers :—Major Baylor and Captain Alexander.

Abadia Hospital is a little north of Berber. It is a larger hospital than the two more northern ones, offering accommodation for 300. The medical staff is as follows :—Lieutenant-Colonel Clery, Major Geoghegan, Major Battersby, Major Marder, Major Allen, Major Braddell, Major Burrows, Captain Girvan, Captain Borrodaile, Lieutenant M. Corkery, Lieutenant Cummins, Lieutenant M'Ardle, and Lieutenant Stallard. The hospital is well found in every respect and is provided with proper hospital clothing and bedding and sheets. A telegram from the Sirdar dated Sept. 5th states that the wounded had arrived safely at Abadia and were doing well.

Atbara Hospital is the most southern stationary hospital and is situated where the river Atbara joins the Nile. It will accommodate as many as 300 patients if tents are also brought into use. The following are the medical officers :—Lieutenant-Colonel Leader, Major Smythe, Major Birrell, Lieutenant S. Archer, and Lieutenant Hopkins.

THE PRESENT OUTLOOK.

We are certainly living in very sensational times. Look which way we will we are encountered by matters of the gravest importance and greatest interest. The late Spanish-American war, the Czar's peace manifesto, the Dreyfus affair and the consequent agitation and unrest of France, the Soudan expedition with the victory of Omdurman and the capture of Khartoum, the partition of China and at the present moment the renewed difficulties in Crete. In India, too, there is much cause for anxiety from the continued prevalence of plague, the still unsettled state of the tribes on the North-west frontier and the perennial question of Indian finance and the coinage. The present is not a very hopeful time for the political economist and the Government of this country will apparently need all its resources and will, at any rate, have to keep its medical services up to the mark as regards numbers and efficiency. Let us hope that matters may have improved before the Congress meets to consider the wise and benevolent proposals of the Czar as to the possibility of limiting the competition of the Powers in the terrible race for naval and military supremacy.

LIEUTENANT-COLONEL SLOGGETT.

We regret to learn that Lieutenant-Colonel A. T. Sloggett, R.A.M.C., was severely wounded in the breast during the splendid battle before Omdurman. Lieutenant-Colonel Sloggett, who is Senior Medical Officer of the First Brigade, is an old fighting hand in Africa. Two years ago he served with the Dongola Expeditionary Force under the present Sirdar and was present in the engagement at Firket and the operations at Hafir. He was mentioned in the despatches and promoted to be Surgeon-Lieutenant-Colonel, and he also received the Fourth Class of the Osmanieh and the Khedive's medal. The latest account as we go to press gives a good report of Colonel Sloggett's wound.

NAPOLEON'S MEDICAL ATTENDANT AT ST. HELENA.

Baron Antomarchi, a grand-nephew of Napoleon's medical attendant at St. Helena, has published in *La Réforme Hebdomadaire* an interesting account of the campaign in Cuba. His great-uncle, Dr. Antomarchi, settled in Cuba in 1834, but died there four years later from yellow fever. His family, however, continued to reside in the island, where they acquired large possessions and enjoyed the society of a number of French planters who had been obliged to fly for refuge to the Queen of the Antilles on the breaking out of the revolution in San Domingo.

DEATHS IN THE SERVICES.

Brigade-Surgeon-Lieutenant-Colonel Benjamin Burland, M.B. (retired), A.M.S., at his residence in London, on August 30th, aged sixty-six years. He entered the Army in 1858, became Surgeon in 1865, Surgeon-Major in 1873, and retired in 1884. He was promoted Staff-Surgeon in consideration of highly meritorious service rendered during the epidemic of yellow fever at Bermuda.

Major George Schuyler Cardew, Royal Army Medical Corps, on August 17th, at Murree, India, aged thirty-seven years.

THE CAMP NEAR OMDURMAN.

The Sirdar and the medical authorities of the Soudan expeditionary army acted very wisely in encamping their victorious forces outside the city of Omdurman. The stench from the corpses of men and beasts which strewed the ground was most offensive and in other respects the city was so insanitary that a very serious outbreak of disease was certain to have occurred had the place been occupied by troops after an exhausting campaign.

THE LATE SPANISH-AMERICAN WAR.

Although the war is over the United States Government will have a good many difficult problems to settle. Questions with regard to the sickness and loss of life alleged to have been caused by the occupation of insanitary camps and want of proper medical arrangements during the late war still occupy the public mind and, as might have been expected, have given rise to much controversy.

The *Army and Navy Gazette* of Sept. 3rd says :—"Fleet-Surgeon A. Gorham's retirement last week brought various changes in the Medical Department. Fleet-Surgeon J. Lyon, of the *Magnificent*, relieves him in the *President*, while Fleet-Surgeon W. R. White, C.B., of the *Hannibal*, goes to the former vessel, and Fleet-Surgeon G. W. Bell, late of the *Crescent*, takes the place of the latter officer."

Surgeon-General Marston, C.B., Army Sanitary Committee, accompanied by Mr. Frederick, the secretary, visited Plymouth yesterday (Sept. 9th) and inspected the buildings recently erected in the citadel.

LITERARY INTELLIGENCE.—Messrs. Archibald Constable and Co. announce the publication of a biographical memoir of the late Dr. E. Schnitzer, known to the world as "Emin Pasha," Governor of the Egyptian Equatorial Province and Scientific Explorer in Central Africa. Emin Pasha's career was in every way remarkable; this, the only official account of his life and work, which is a slightly abbreviated translation from the German edition, compiled by his brother-in-law, will be particularly interesting at the present moment as giving many a side-light on German colonial methods at the time when the Anglo-Egyptian expedition has reached Khartoum. Dr. R. W. Felkin, a personal friend and for long a correspondent of Emin, has written an introduction to the English edition of the book explaining what assistance Emin asked for from Britain and how his requests were met.—The Scientific Press, Limited, will shortly publish an Atlas of Bacteriology, by Charles Slater, M.D. Cantab., and E. J. Spitta, L.R.C.P. Lond., M.R.C.S. Eng. The book will be copiously illustrated with photographs.

"Audi alteram partem."

SAWDUST URINALS.

To the Editors of THE LANCET.

SIRS,—Some few years since I took occasion to direct attention to the value of sawdust in rendering urine filtered through it thoroughly aseptic; and the present dearth of water for sanitary purposes is my reason for asking you to allow me to direct the attention of sanitary authorities to this fact; and to advise them to give sawdust urinals a trial, as my increasing experience in this matter leads me to say that when properly constructed they are thoroughly satisfactory. There should always be complete exposure to light and air, but protection from rain is advisable. No better urinal can be devised than a tall bushel basket filled with deal sawdust and placed in a shed. Such a urinal in dry hot weather will take a surprising amount of urine without affording any filtrate, owing to the freedom of evaporation. If the use of such a urinal be not excessive and if it be stirred occasionally it will increase in effectiveness with use. If the nose be placed close to the surface of such a urinal it will be found to be strongly ammoniacal, but I have never known one to be foul. The filtrate is usually slightly aromatic and has never shown any disposition to putrefy. I do not know how often the sawdust needs to be changed. I lately examined the sawdust which had been used for three months in the urinal of a country public-house and I found it absolutely free from all offensive odour.

When such urinals are not made of basket-work they must have an outlet at the bottom through which the aseptic filtrate may escape to the drain. Those who may wish for further details as to the construction of sawdust urinals will find them in my little book, "The Dwelling House," which is published by Longmans.

I am, Sirs, yours faithfully,

Sept. 2nd, 1898. G. V. POORE, M.D.

"THE PLAISTOW MATERNITY CHARITY."

To the Editors of THE LANCET.

SIRS,—With reference to your remarks on the Plaistow Maternity Charity" in Howard's-road, Plaistow, in THE LANCET of August 27th, I beg to state that St. Mary's Day Nursery and Hospital for Sick Children, Plaistow, E., is in no way connected with the St. Mary's Children's Hospital, Plaistow, E.

I am, Sirs, yours faithfully,

W. W. FARNFIELD, Resident Medical Officer.

St. Mary's Children's Hospital, Plaistow, E., August 30th, 1898.

To the Editors of THE LANCET.

SIRS,—In the article in THE LANCET of August 27th referring to the East Suburban Medical Protection Society your contributor deals with nursing charities to some extent from a medical man's point of view, and passes certain strictures which are wholly undeserved upon the Maternity Charity and District Nurses' Home, Plaistow. It is no part of your aim to deal with the subject from the patient's point of view, and therefore any observations upon that head would be out of place. In the interest, however, of the charity to which you refer, there are certain misstatements of fact in that article which ought to be corrected. In all ordinary cases—that is to say, in all the district nursing and most of the midwifery—no payment whatever is received, and the frequent reference to fees in your article is most misleading. Further, as regards the district nursing, no patient is nursed unless attended by a medical man, except in a few trifling cases, such as cut fingers, for which no doctor would be called in. As to the case of people who have been attended who might be able to afford a nurse, it may be pointed out that these cases are extremely rare, numbering certainly not more than 2 in every 1000 cases attended, and in each case there has been a special reason for the attendance.

As regards the midwifery work it should be observed that in the great majority of the cases no payment is made, and that the fee, in such cases where it is payable, was raised from 5*s.* to 10*s.* with a view to meeting certain objections advanced by this medical protection society. The sum of 10*s.* was fixed upon because this pays the whole expense of the attendance, so that it is a misrepresentation to suggest that the patient gets any benefit out of the donations to the charity or, on the other hand, that the charity makes any profit out of the putient. The right of the patient to choose between a midwife and a local medical man, and where she insists on a midwife—as many poor women will—the desirability of ensuring that a properly certificated midwife shall be in attendance, are matters which are beside the point of your article, though not in themselves unimportant.

In conclusion, it is desirable to state a fact, which is probably well known to your contributor, that the advantage to the local practitioners of the presence of this charity is very great. The local medical men are constantly asking for nurses to attend their cases and returning warm thanks for their being sent; the more important practitioners are enabled in this way to attend cases which must otherwise go to hospital; they often have patients sent them by the nurses and, in fact, their demands for nursing attendance tax to the utmost the resources of the charity.

I am, Sirs, yours faithfully,

Inner Temple, August 30th, 1898. ARTHUR PRITCHARD.

THE PERSHORE GUARDIANS AND THEIR POOR-LAW MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—The Pershore Guardians, at the last annual election of their medical officers, advertised for candidates who would waive all claim to superannuation. The Local Government Board, upon representation being made to them, informed the guardians that the arrangement was not one to which they could consent. It would seem now, according to a report of the proceedings of the guardians in the *Evesham Journal and Four Shires Advertiser*, to be the intention of certain members of that board to oust at least one of their medical officers, who has served them for nearly thirty years, by appointing at their next election a medical man they would get to "reside" in the district, and thus unless the Local Government Board again interfere he will not only lose his appointment but have the annoyance of being opposed under most unfair circumstances.

I am, Sirs, yours faithfully,

ARTHUR GREENWOOD,

Honorary Secretary, Poor-Law Medical Officers' Association, 3, Copthall-avenue, London Wall.

August 31st, 1898.

VITALITY.[1]

To the Editors of THE LANCET.

SIRS,—Dr. Harry Campbell will, I hope, pardon me for this late reply. Having recently occupied so many columns of THE LANCET I did not like to ask for space until the last of "Vitality" was published. Perhaps I may be allowed to remark that in replying to those who may differ from me I shall be as brief as possible and shall compress what I may deem it right to say in less than half a column of the journal.

If, as Dr. Harry Campbell considers, vitality is to be regarded "as a peculiar play of forces belonging to the inanimate world" I venture to inquire what it is that governs, controls, and regulates the particular forces of that very small portion of the matter of the inanimate part of our world which alone has entered or ever will enter into the composition of living things.

Although I consider that the "immaterial" does act, ever has acted, and will continue to act upon the "material," I cannot think that I occupy "a position as untenable as that of the spiritualists" which has been assigned to me by Dr. Harry Campbell, who also tells your readers that my assumption "that bioplasm is structureless" is "wholly *illogical*," because forsooth "*in our journey into the world of the infinitesimal we come sooner or later to a point at which we cease to detect structure!*" (The italics are mine.) I

[1] In reply to Dr. Harry Campbell's letter to THE LANCET of July 16th.

Digitized by Google

cannot say, with Dr. Harry Campbell, "I believe in the spontaneous evolution of life," because I do not, never did, and never can believe in anything of the kind.

If Dr. Harry Campbell will define the characters of his "cell," and tell us what it does, what it looks like when magnified about 250 linear, how it began life, how it works, and what happens when it dies, I will do my best to convince your readers that facts demonstrated are to be accounted for, if we only begin with structureless bioplasm and go on to formed material.

In this discussion concerning the nature of life—Vitality—I must beg opponents of any views of mine not to include me in any class or section whatever of believers, unbelievers, materialists or spiritualists, sceptics or agnostics (who beat us all in *knowing*), for among those who devote themselves to science and the real, and are influenced by reason in their search after truth, are members of all "denominations" under the sun.

Let us, then, begin by considering the *matter that is alive* and the *formed material*—bioplasm and tissue—the "energy" of the living body and the "energy" of the dead body—the well-constructed laboratory with its intelligent working chemists and physicists, and the *living laboratory* with the chemical and physical changes therein, and then perhaps we may be ready to begin to prepare for "our journey into the infinitesimal," or rather "into" that infinitesimal portion of it that is *alive*.—I am, Sirs, yours faithfully,

Grosvenor-street, W., Sept. 2nd, 1898. LIONEL BEALE.

HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me space to ask your readers whether they are of opinion that it would be desirable and useful to hold a congress in London some time during the ensuing year to discuss the following subjects: (1) The reform of the out-patient department of hospitals; (2) the desirability of converting all free dispensaries into provident dispensaries; (3) the best method of conducting provident dispensaries. I may say at once that the promotion of such a congress would entail a good deal of expense and we should be compelled to appeal to the profession for special help to carry it out. The Hospital Reform Association has been able, with a very limited income, to arouse public interest in the hospital question, and has to a certain extent been the means of bringing about some tangible reforms. Much work, however, remains to be done, and it would be a pity that it should not be accomplished for the want of proper support from the profession.

I am, Sirs, your obedient servant,

Cardiff, Sept. 6th, 1898. T. GARRETT HORDER.

THE CONGRESS OF PHYSIOLOGY.

(BY OUR OWN CORRESPONDENT.)

THE Fourth Triennial Congress of Physiologists took place at Cambridge University between August 23rd and 26th and was an unqualified success, though the lay press hardly discovered its existence. It was perhaps partly overshadowed by the better-known Congress of Zoology, whose 400 members held their meetings during the same week. But while they admitted many amateurs to their sections the physiologists were rigorous in only receiving those connected with their own subject and the allied sciences. So it happened that out of 232 members 154 were professors or lecturers, and 16 foreign countries were represented, including Egypt, India, and Japan. It is difficult out of 91 communications to know which to comment upon, but it seemed to be the general opinion of the foreign members that the English papers were of good value and of commendable brevity and lucidity.

The official business of the Congress was formally opened by a few pithy words of welcome and direction from the President, Professor FOSTER, on Tuesday morning, August 23rd. The President intimated that the object of the meeting was primarily to see actual experiments rather than to listen to verbal or even receive merely pictorial demonstrations.

An early paper of much interest was one by Professor KOSSEL (Marburg) on the Proteid Molecule. The hexon bases into which the molecule can be split are found in various amounts in different species of proteids. Their quantity is greatest in the newly recognised proteid histon and they are least in quantities in elastin. The physiological value of these substances differs, therefore, considerably within the limits of the albuminous group.

Professor BEER (Vienna) showed a number of experiments demonstrating the mode of production of visual accommodation in various groups of animals. The mechanism employed in the human eye is not that universally obtaining even in vertebrata. The same object is attained in amphibians and snakes by the shifting forward of the lens when objects near at hand have to be focussed. In fishes the active accommodation is not for near vision but for far vision, and in them a muscle, the retractor lentis, draws the lens towards the retina for vision of distant objects. Some vertebrates, even mammals, have no power of accommodation; the water tortoises have a relatively enormous accommodative range.

Professor BIEDL (Vienna) demonstrated the production of glycosuria by ligation of the thoracic duct and the alleviation of the symptom by the intravenous injection of lymph.

Dr. BRUNTON BLAIKIE exhibited specimens of urea obtained from normal mammalian muscle freed from blood.

Professor DENYS (Louvain) brought forward experiments showing the bactericidal power of extracts of leucocytes from the marrow and the absence of such power in leucocytes of the lymph glands, &c.

Professor HEGER and Dr. DEUWOR (Brussels) contributed work upon the alterations in the morphological appearance of the neurons of the cortex of the brain brought about by anæsthetic and narcotic drugs and by the winter sleep of hibernating animals. The interesting point has been proved by Professor von Frey (Zürich) that in order to evoke a sensation of touch the larger the surface of contact the relatively more intense must be the pressure per unit of the surface of application.

Two significant experiments were shown by Professor SHERRINGTON, F.R.S. (Liverpool): (1) the striking inhibition of the tonus of the extensor muscles of the knee-joint and the consequent abolition of the knee-jerk obtained by electrically stimulating or even gently kneading the flexor muscles of the knee; and (2), in conjunction with Dr. H. E. HERING (Prague), the inhibition of various muscles of the limbs and trunk obtained by excitation of points of the cortex of the brain. It was shown for a large number of muscle groups that at least two cortical centres for each exist. From one of these contraction can be regularly elicited and from the other relaxation.

Professor HAHN (Munich) showed that by injection of extracts of cholera bacilli and of typhoid bacilli into guinea-pigs specific immunity against intra-peritoneal infection with those bacilli can be obtained.

Professor TOWNSEND PORTER (Harvard, Boston, U.S.A.) showed some remarkable experiments on the mammalian heart. The heart removed from a recently killed dog, washed clean of blood, and then supplied with defibrinated blood or even with blood serum under high pressure of oxygen recommences to beat. Even small pieces of the ventricle of the thus excised heart will go on contracting forcibly and regularly for many hours.

Dr. LEONARD HILL (London) exhibited a simple and accurate sphygmometer for recording the blood-pressure in the human radial artery. Dr. Hill also demonstrated experiments illustrating the great influence of gravity upon the circulation. He showed how by adoption of suitable postures or by use of a bath or of compression of the abdomen the dangers and ill effects can be removed. The arterial pressure is restored, the heart fills, and respiration becomes re-established.

Dr. F. G. HOPKINS (London) and Mr. W. B. HOPE detailed observations on the dietetic precursors of the uric acid of urine. They pointed out that the ascription of all uric acid production in the mammal to the disintegration of nucleins is an over-hasty conclusion.

An important addition to micro-chemistry was made by Professor MACALLUM (Toronto) in the demonstration of a new and reliable method for the detection of phosphorus in animal and vegetable cells. The tissues after being treated with molybdate of ammonia in nitric acid are acted on by phenylhydrazin hydrochloride. To prevent confusion their lecithin is previously extracted with hot alcohol. The

Digitized by Google

phosphorus compounds give a dark-green reaction. The method reveals phosphorus in the chromatin of all nuclei, in all nucleoli, in the zyanogen granules of pancreatic cells, in the colloid material of the thyroid and in the outer limbs of the rods and cones of the retina.

Professor WALLER, F.R.S., brought forward the continuation of his work on the influence of salts on the electro-mobility of nerve fibres. The predominant moiety of a salt in its action upon nerve is the basic or electro-positive element—e.g., any potassium salt is more effective than any sodium salt.

Dr. BUDGETT (St. Louis, U.S.A.) communicated experiments on the physical absorption of salt solutions by egg-membranes.

Professor VITZOU (Bucharest) reported experiments showing the existence of visual power in the monkey after total ablation of both the occipital lobes of the brain. The effect of injection of neurin and allied substances upon the circulation was shown by Professor HALLIBURTON, F.R.S., and Dr. MOTT, F.R.S,, in prosecution of their research upon toxic substances occurring in certain classes of diseases of the central nervous system.

Dr. LEE (New York) showed that of the two supposed causes of muscle-fatigue—viz., decrease of contractile substance and accumulation of fatigue products with poisoning of the muscle thereby—the former plays no part, the latter being the sole factor. His attempts to demonstrate histological differences between resting and fatigued muscle had given only negative results.

An excellent demonstration of the electric changes in the phrenic nerve which accompany its normal periodic activity was given by Professor WAYMOUTH REID, F.R.S. (Dundee), and Dr. J. MACDONALD.

Professor BÉDART (Lille) reported on the production of a flow of secretion from the mammary glands by electrification of the skin over the gland.

Mr. LANGLEY (Cambridge) showed a cat the end of the vagus nerve of which had been joined to the sympathetic nerve 64 days ago. Both nerves had been ligatured with horsehair and 1 in. of the nerves above the ligature carefully excised. The central end of the vagus was then turned forward to lie in contact with the peripheral end of the cervical sympathetic. At the meeting the vagus was cut near the skull and its peripheral end stimulated, when all present could plainly see that a regeneration had taken place, the eye opened, the nictitating membrane retracted, the pupil dilated, and there were in short produced the ordinary effects of stimulating the cervical sympathetic. This experiment proves that fibres of nerves can be diverted for other purposes and vaso-dilators be converted into vaso-constrictors. During the experiment an injection of nicotin prevented the vagus but not the superior cervical ganglion from acting.

Professor MAREY (Paris) pleaded the need of an international commission to unify and control recording physiological instruments such as manometers, myographs, sphygmographs, &c., in order to bring results up to the uniform standard which has been accepted in physics.

Professor HEYMANS (Gand) showed that various organic substances of the sulphur group can prevent or cure poisoning produced by fatal doses of nitryls and cyanides. A rabbit injected with the antidote and immediately afterwards with the poison remained lively and well, while a control rabbit without the antidote was killed in half an hour, and a third rabbit which received the same dose of poison without the antidote was reduced to a moribund state and brought back to life again by a dose of the antidote.

Professor SCHÄFER (London) gave a valuable account of his experiments on the alleged sensory functions of the motor cortex cerebri of the monkey. He has made 30 experiments upon the area connected with movements of the face, the leg, combined arm and leg, and upon the gyrus fornicatus. An important point noticed in the face area observations is that, although the cheek-pouch was paralysed and became filled with food, the animal was conscious of its presence and occasionally emptied it by pressing it against the shoulder or by forcing the contents out with the hand. Some of the monkeys were shown to the Neurological Society and were tested by several of its members a year ago. The result, in short, shows that complete voluntary motor paralysis of a part may be produced by a cortical lesion without perceptible loss of tactile sensibility. It cannot, therefore, be the case that the motor paralysis which is produced by a lesion of the Rolandic area is due to a sensory disturbance. And it also follows that tactile sensibility is not localised in the same part of the cortex from which voluntary motor impulses directly emanate. Hemianæsthesia sometimes results from an extensive lesion of the motor cortex; this is, however, not local but general, and is due to the vascular and mechanical disturbance produced upon the whole side of the brain by the establishment of the lesion. That this is the case is shown by the fact that it is generally accompanied by hemiopia, though in none of the experiments was the visual cortical area directly involved in the lesion. Five monkeys were operated on in this way: having exposed the upper Rolandic region the leg area in the gyrus marginalis was completely severed by a cut passing as far down as the calloso-marginal sulcus and deep enough to sever all the fibres passing from the cortex to the centrum ovale. In no case did the lesion produce anything more than a temporary sensory disturbance; the opposite leg was always completely paralysed, although after a time "associated movements" returned. This tends to show that the hemianæsthesia of former operations must have been correlated with disturbance of some part of the cortex other than the motor region and was probably indicative of a general disturbance of the whole hemisphere, involving perhaps the thalamus.

Professor BOWDITCH (Harvard) begged members to sign a protest in favour of the moderate use of alcohol to counteract the efforts of too zealous teetotallers in America who had persuaded the Government to introduce into schools and school-books the doctrine that alcohol is a poisonous substance which can only do harm and never do good to the human body.

Professor BOYCE (Liverpool) read a paper illustrated with many lantern slides on the Central Nervous System of Birds. Two constant physiological movements are obtained by stimulating the surface of their hemispheres—viz., contraction of the opposite pupil from stimulation about the middle of the mesial wall, and rotation of the head and neck and deglutition from stimulation of a small area on the lateral aspect. By removing the anterior or posterior portion of the cerebral hemisphere marked deficiency of vision in the opposite eye is caused but no kind of motor defect. If the injury be to one optic vesicle marked partial blindness in the opposite eye occurs, and if injury be very severe the bird becomes unable to stand and lies on its back continually. If both central hemispheres are destroyed the bird is very inert, does not peck corn and must be fed, does not pay any attention to objects moved in front of its eyes, but in walking avoids obstacles and obtains some support in the air by its wings, but cannot fly properly. To show how completely the brain is an optic organ absolute blindness could never be produced, for the acerebral pigeon avoids obstacles, and this is the case also when, together with removal of one hemisphere and consequent blindness on the opposite side, the eye of the same side is enucleated.

Professor KRONECKER (Berne) read several papers for himself and others, of which want of space forbids further mention.

The five physiologists chosen by the University to receive the honorary degree of Doctor of Science were Bowditch, "from the other Cambridge," known for his work on heart, muscle, nerves, &c.; Golgi (Pavia), renowned for his interest in malaria; Kronecker (Berne) and Marey (Paris), both of whom have adapted many physical instruments to physiology; and Kühne of Heidelberg whose labours are known in connexion with nerves and muscles.

The Public Orator employed the modern pronunciation of Latin, but our medical colleague the Vice-Chancellor was loyal to the English methods. Great credit is due to the president, committee, and honorary secretaries for making the meeting a great success. The only unfriendly criticism made was that the exhibition of instruments and apparatus was a very poor one. The evening entertainments were shared by the zoologists, which made a pleasant variation. They consisted of a reception by the mayor, a *fête champêtre* given by the Vice-Chancellor at Downing College, a conversazione in the Fitzwilliam Museum, a garden party in the botanical gardens and a subscription banquet. At the final meeting grateful thanks were accorded to all the kind hosts. The great feature of the Cambridge congress for most of the visitors was that they were nearly all housed in Trinity, Trinity Hall and Caius colleges, and they were allowed to obtain an intimate insight into the inner life of the Cambridge dons.

At the final session of the Congress it was resolved that

Digitized by Google

the next meeting (1901) should be held at Turin under the presidency of Professor Mosso. The following were elected to act as an organising committee:—Professor Bohr (Copenhagen), Professor Bowditch (Boston, U.S.A.), Professor Dastre (Paris), Professor Foster (Cambridge), Professor Fredericq (Liège), Professor Grützer (Tübingen), Professor Kronecker (Bern), Professor Kühne (Heidelberg), Professor Mosso (Turin), Professor Sherrington (Liverpool), and Professor Wedenskij (St. Petersburg).

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Fresh Increase of Plague. — Postponement of the Great Improvement Scheme for Bombay. — Inoculation and Vaccination.—More Regulations about Plague.

THE increasing death-rate from plague in Bombay city seems to foreshadow the early occurrence of a third outbreak. 85 deaths from plague have been registered during the past week—an increase of 23 on the previous record. The almost entire absence of cholera is still a remarkable feature in the returns. While last year the returns of plague were probably under-estimated in consequence of the concealment of cases there is reason to believe that under the present system of administration all the cases are recorded. In Calcutta it has been feared for some time past that cases of plague have been concealed. As the total mortality, however, has been small the unreported cases must have been very few. The discovery of two natives dead and two more in a dying state in one house on August 10th gives proof of this concealment. The disease is increasing in the Deccan. As many as 90 fresh cases and 62 deaths were reported at Hubli for August 8th. In the Bhore State also it is increasing. It is hardly likely that Poona will escape another visitation and already some suspicious cases have been discovered at Poona station.

The indefinite postponement of the great improvement scheme for Bombay has caused great disappointment. At one time the matter was put forward as one of great urgency and promised an early prospect of its fulfilment. Rumour has it that jealousy is the cause of this urgent and great reform in the western city being postponed. It might seem childish to English minds to suggest that such an influence could prevail, but those who know India best say that it is not only possible but probable. The third reading of the Bill was taken in April and while numerous references have been made in matters of detail it still requires the final sanction, and the final sanction does not come.

No further results have been proclaimed about "curative" serum. Prophylactic inoculation proceeds but slowly. It is unknown how long the partial protection lasts—in all probability but a few months. A few experiments on animals would afford some clue on this point, but nothing seems to have been done. Being merely a temporary toxin poisoning there is of course no comparison with vaccination. The latter practice was carried out in Bombay to the extent of 84 per cent. Considering the difficulties of registration it shows that in India at any rate the people have learnt to place confidence in its value. It is to be hoped at any rate that the Eastern mind will not require a clause to satisfy its conscience. Amongst the unvaccinated emigrants, chiefly from Africa, small-pox is most terrible.

The vacillation of the Government with respect to plague administration is again shown by the issue of a fresh series of regulations, dated August 12th, giving special powers and directions to the Municipal Commissioner of Bombay. It will be remembered that after the riots all coercive measures were suspended and that practically from that date little was done except house cleansing and disinfection. Now, however, the removal to hospital of persons suffering from plague is re-enacted. Powers are given to a specially appointed Deputy-Commissioner to inspect and have cleansed any insanitary buildings, to take such measures as he shall think fit where any dangerous disease is suspected to exist in order to prevent its spread, to close any well or tank the water of which is likely to cause the spread of any dangerous disease, and to have destroyed any hut or shed, bedding, clothing, or other articles likely to spread disease. The new regulations are, in fact, a re-instatement of the powers of the late Plague Committee. A special medical officer is appointed for plague operations. It is too soon perhaps to calculate upon the effect of such measures. Suffice it to say that if they be carried out with the strictness of the previous authorities more troubles may be anticipated.

August 13th.

The Bombay Improvement Scheme. — The Milk-supply of Bombay.—Death of Dr. K. N. Bahadurji.—The Plague and Typhoid Fever in India.

The Act for the great Bombay Improvement Scheme has at last received the final sanction, so that there is no cause why the structural improvement of Bombay should not be commenced at once. While the great alterations proposed will improve the city in many ways it must not be imagined that it will make Bombay a healthy city or have any effect on the plague. The conditions of existence of the great mass of the natives are such that only radical building Acts, housing Acts, and almost universal alteration of drainage arrangements could improve their state of health. Bombay will be beautified, communications between one part of the city and another will be facilitated, the streets will be opened out, and "artisans dwellings" constructed for a certain number of the people, but these things, while comprising immense improvements, will not strike at the inner unhealthy life of the people. In THE LANCET of Feb. 26th the state in which hundreds of thousands of people live in the crowded parts of Bombay was described. Perhaps the most crying evil is the overcrowding and the general want of ventilation in the dwellings. One effect of this is the extremely high death-rate from phthisis. It must be admitted that to put a large and overcrowded Indian city on a proper sanitary footing and to adapt the principles of western civilisation to the circumstances of this country is an almost impossible undertaking. At any rate, a sanitary miracle cannot be performed, so that it is necessary to remind enthusiasts that improvement of the public health must necessarily be slow and that they must be satisfied with the prospective advantages in many years to come.

The milk-supply of Bombay is another matter which requires urgent attention. It is obvious that the dairies and cattle-sheds should be subject to rules and regulations the breach of which should be punishable, and that they should be periodically visited by competent inspectors. At present this is far from being the case, the cattle for the most part being housed and kept in a most filthy state. There is not sufficient protection against dirt and there is practically none against fraud. These strictures do not apply to one or two well-managed dairies, but the great mass of the milk-supply is open to this condemnation.

I record with much regret the death, at the early age of thirty-eight years, of Dr. K. N. Bahadurji, the leading Parsee practitioner in Bombay. He was a M.D. Lond. and well-known for his advocacy of certain medical reforms, more especially the grievances of native medical graduates.

Whilst typhoid fever is so common and so fatal amongst the British in India it has been asserted that from this disease the natives are free. On the other hand it has been argued that being common amongst young children it is in consequence not often seen amongst the adult population. From cases I have seen I believe there is an explanation for these apparently contradictory statements. In the first place the bowel symptoms in natives suffering from typhoid fever are but slightly marked, so it is probable that the general symptoms existing alone have caused it to be confounded with other diseases. It is generally admitted that there are a large class of fevers in India in which it is almost impossible to make an exact differentiation. These two facts explain the absence of a correct diagnosis in a very large number of cases. In the second place typhoid fever is not so fatal among the native population and when the patient succumbs it is more frequently due to what is apparently a complication. The illness is therefore often probably recorded as a local disease although accompanied by a general fever. The essential point of difference, however, lies in the comparatively slight abdominal symptoms. If these statements be confirmed they will explain why it is that typhoid fever has not hitherto been recognised as common amongst the native population. I have reason to believe that at the present time typhoid fever is prevalent in Bombay, that many of the deaths returned as from "fever" are due to this cause, and that the prevailing diarrhœa has a similar origin. At the same time the total

Digitized by Google

deaths from fever are considerably below the average of previous years.

In view of the possibility that plague will become epidemic in Calcutta during the colder season elaborate precautions are being taken by the authorities. The health officer has granted licences for 974 ward, family, and caste hospitals. They are divided thus: family hospitals, 957; ward hospitals, 11; and caste hospitals, 6. The reported mortality from plague in Calcutta up to date is over 150. Outside the Bombay Presidency Calcutta is the only place affected, though an isolated case has been reported from the Punjab and 2 imported cases in Madras. In the Bombay Presidency, Bombay City and Belgaum, Dharwar, Surat and Thana districts are most affected. In Bombay City 101 deaths from plague were registered during the past week. Relapsing fever still continues, 16 deaths having been recorded. The mean death-rate for Bombay in the month of August is about 40 per 1000; at the present time it is 44·4 per 1000.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Deaths under Anæsthetics.

TWO instances of death during the administration of anæsthetics have lately occurred in this neighbourhood. One was that of a boy, aged fifteen years, who died on August 10th at Redditch when chloroform was given for an operation on a diseased hip. In this case Dr. Page, who gave the chloroform with a modification of Junker's inhaler, stated that the amount given was 80 minims, the operation lasting 25 minutes. The deceased was a fragile, delicate boy, but examination beforehand showed no contra-indication to the use of chloroform. The post-mortem examination showed no unusual signs, the heart being natural but contracted. A verdict of "Death from syncope following the administration of chloroform" was recorded. The second case occurred at the Queen's Hospital on August 24th. The patient was a woman, aged thirty-nine years, the subject of cancer. An abdominal section was about to be performed but the patient died before it was commenced. Here the anæsthetic was chloroform and ether in mixture and was given by one of the house surgeons. Preliminary examination failed to find any abnormality in the heart. At a post-mortem examination it was found to be fatty and flabby. A verdict of "Death while under an anæsthetic properly administered" was given, the cause being attributed to syncope and heart failure.

The Viewing of Bodies at Inquests.

This well-worn subject was the occasion of some remarks from the coroner for the city (Mr. I. Bradley) at his court on August 17th. The question has apparently not been definitely settled whether the viewing of the body at an inquest is obligatory or not. The Home Secretary has not expressed himself authoritatively upon the matter. No doubt the primary object of the viewing was to assist at the inquest in the detection of crime—to find out when and where and by what means the deceased came to his death—"of whose body you shall have the view." The perfunctory way in which the viewing is performed and the distaste it occasions, particularly during the recent hot weather, has been the subject of much animadversion on the part of jurors. As long as the law remains so wanting in precision of interpretation in this direction it cannot be a matter of surprise that this repugnant duty causes so much disgust among those whose duty calls them to fulfil the privileges of citizenship.

August 30th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Henshaw's Blind Asylum and the Guardians.

THE quarterly meeting of the old and valuable institution well known in the Manchester district as Henshaw's Blind Asylum was held the other week. Mr. S. L. Helm in moving the adoption of the report said that at present there were 193 inmates—62 men, 44 boys, 44 women, and 43 girls. All but 4 of them had had summer holidays, the board providing funds for 48 who had no means of their own. For many of the blind a home is provided for life. Three of the oldest inmates died during the last quarter, one of whom was admitted in 1845, another in 1849, and the third in 1865. They are taught various occupations enabling many of them to earn their own living and to return to their friends. The Manchester guardians have hitherto subscribed 5 guineas a year to the asylum, in return for which they became governors and had the power of nominating candidates for admission. There are at present several inmates nominated by the guardians, for whom a charge of from 4*s.* to 6*s.* a week is made, but even the larger sum does not meet the cost incurred in their support. Now, however, according to the newspaper reports, the guardians have decided to withhold their subscription. Under these circumstances Mr. Helm said it would be his duty to bring the matter before the board of management in order that they might consider the propriety of raising the weekly charge for these inmates to recoup themselves for the loss of the 5 guineas. The guardians would no doubt be charged the rate asked from others. They could withdraw their nominees, "but as the institution was usually full, and there were at present a number of candidates waiting for admission, that was not a matter with regard to which the board of governors need feel immediate concern." He said they could not allow the institution to suffer through the action of the guardians. The asylum is a voluntary institution and "by no means compelled to find room for the candidates sent by the guardians." It will be unfortunate if there should be any misunderstanding between the asylum and the guardians, for the latter will have a serious undertaking before them if they are to maintain, instruct, and educate their nominees in the various occupations open to the blind as thoroughly and efficiently as is now done at the asylum. They have neither the special skill acquired by long experience nor the necessary appliances, nor will their nominees escape from the tainted social atmosphere of the workhouse.

Enlargement of Monsall Fever Hospital.

The City Council of Manchester having applied to the Local Government Board for sanction to borrow £27,500 for the alteration and enlargement of the Monsall Hospital, an inquiry was held in the town-hall on August 23rd by Mr. W. W. E. Fletcher, M.B. It may be remembered that the hospital was recently taken over by the Corporation from the Infirmary. It is used for the various infectious diseases exclusive of small-pox, which will be treated elsewhere. At present neighbouring outside authorities send cases to the hospital for so much per head, but this arrangement will terminate on June 24th next, after which date it will be used exclusively as a Manchester hospital. Thirty acres of additional land are to be utilised. The inspector said that if separate accommodation were provided for small-pox cases he did not see that there would be any difficulty with regard to granting the corporation's application.

Open Spaces for Manchester.

The Lord Mayor on August 26th formally opened a recreation ground presented by Mr. F. E. Loyd to the residents of Cheetham. Plots are reserved for bowls and lawn-tennis, and a playground is set apart for children. The Lord Mayor said it was the thirty-eighth park or open space under the control of the Parks Committee, and claimed that Manchester was as well off for parks as any city in the kingdom. The *Manchester Guardian*, however, took him to task the next day, saying that there is scarcely any great city worse off, a proposition which unfortunately can be sustained by figures. Two years ago it pointed out that Glasgow had 817 acres of open space for public recreation, Liverpool nearly 700 acres, Birmingham 450 acres, Leeds a single park of more than 400 acres besides smaller parks and recreation grounds, while Manchester had only 312 acres. Some few acres have been added since, but there is still plenty of opportunity for wealthy citizens to give some brightness to the depressing life of the crowded population by adding to the scanty area of open spaces in the city. Nor is Manchester, as the Lord Mayor said, one of the healthiest of cities. The death-rate, though lower than it was, is still high, and while the suburbs are fairly healthy the average is made up by the appalling death-rate of some of its poorest quarters, which, as the *Manchester Guardian* says, "disgraces the city." It must in fairness be said, however, that we are reaping the fruits of municipal ignorance and neglect in years gone by and that earnest and

Digitized by Google

intelligent efforts are now made to remedy the mischief caused by old errors.

Unsound Meat.

At the Salford police-court on August 26th Messrs. Reid Brothers, potted meat manufacturers, were summoned for having unsound meat on their premises. On August 4th a cart in the yard contained the heads of sixty-four beasts "unsound and stinking," and in a storehouse were eighteen tongues also unsound. The two defendants were fined £20 each and costs and also £3 3*s.* extra costs.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool City Hospitals: Contemplated Extensions.

THE members of the Port Sanitary and Hospitals Committee of the City Council made their annual inspection of the several infectious diseases hospitals under corporate management on Sept. 2nd. The Fazakerley site was the first to be visited. The site was acquired by the committee at a cost of £37,000 as a safeguard against the dislodgment of the Parkhill Hospital, which is let to the corporation by the Mersey Docks and Harbour Board, and which it is possible may be required by the latter body. The site consists of 113 acres and will accommodate 300 beds, 80 more than are provided at the Parkhill Hospital. The party then proceeded to visit the offices of the Port Sanitary staff at the pier-head, thence proceeding to the Grafton-street and Parkhill Hospitals. The Grafton-street institution is probably one of the most complete of its kind in the kingdom. Extensions are in contemplation at Mill-lane, Old Swan, at a cost of £40,000, where it is proposed to erect two pavilions to contain 80 beds. As time goes on the committee will be enabled to deal with all acute cases of infectious diseases and to draft convalescent cases to Fazakerley. The chairman, Dr. Thomas Clarke, pointed out that with regard to small-pox the new Vaccination Act did not accord with the views of the committee, as in a limited time unvaccinated cases would probably predominate. That was one of the strongest arguments which could be used in favour of the erection of additional small-pox hospital accommodation. Dr. Hope pointed out that the parish of Liverpool was the most extensively vaccinated parish in England. The latest published returns showed that only 4 per cent. of children born in Liverpool were not accounted for in regard to vaccination. In West Derby the rate was 7 per cent. and in Toxteth Park about 9 per cent. The members of the committee sat down to luncheon at the Parkhill Hospital, which was presided over by Dr. Thomas Clarke, the chairman of the Committee.

The Purity of the Liverpool Water-supply.

It is satisfactory to know that the Vyrnwy water is not "particularly rich in typhoid germs" as was asserted by a speaker at a recent meeting of the Chester Waterworks Company. Dr. Hope, the medical officer of health of Liverpool, informed the Water Committee of the Liverpool City Council that all the reports made by Professor Boyce during the past twelve months proved that the Vyrnwy water was of exceptional purity and not a typhoid organism or anything allied to it had ever been found in it. The members of the committee expressed themselves quite satisfied that the statement was absolutely without foundation and that Liverpool was very fortunate in having such a wholesome water-supply.

Death of Mr. John Wallace, M.D., L.R.C.S. Edin.

The death of Dr. John Wallace, the Professor of Midwifery at University College, Liverpool, and consulting gynæcological surgeon to the Liverpool Royal Infirmary, took place on Sept. 1st from an attack of gastritis. Dr. Wallace had only been confined to the house for a few days, his death being so unexpected that the wedding of his son, Dr. Arthur J. Wallace, which was fixed for Sept. 1st, was not postponed. However, during the evening of Sept. 1st, an attack of hæmatemesis supervened, causing so much prostration that Dr. Wallace succumbed before midnight. Dr. Wallace graduated as Doctor of Medicine at the University of Edinburgh in 1861, having been a pupil of the late Sir James Y. Simpson. He settled in Liverpool nearly thirty years ago and devoted himself to obstetric practice. Prior to the foundation of University College, Liverpool, Dr. Wallace was lecturer on midwifery at the old Liverpool School of Medicine and afterwards became its professor at University College. In 1878 he was appointed gynæcological surgeon to the Thornton Wards of the Liverpool Royal Infirmary upon the death of the late Mr. A. B. Steele, the first gynæcologist, which he resigned at the last annual meeting, having attained the limit of age of sixty years. He was thereupon appointed consulting gynæcological surgeon. He was also an examiner in obstetric medicine at the Victoria University and a past president of the North of England Obstetric and Gynæcological Society. Dr. Wallace leaves three sons and two daughters; his eldest son, Dr. Arthur J. Wallace, is the assistant lecturer and demonstrator in midwifery and gynæcology at University College, Liverpool. The remains were cremated at Anfield Cemetery on Sept. 5th, prior to which a funeral service was held at St. Andrew's Church, Rodney-street, which was attended by a large number of Dr. Wallace's former colleagues and other friends.

The New Vaccination Act: the First Case in Liverpool.

The first "conscientious objector" to the practice of vaccination appeared at the Liverpool Police-court before Mr. Kinghorn, the deputy stipendiary magistrate, a few days ago. The applicant, a young married man, aged twenty-three years, applied for a certificate of exemption on the grounds that he "did not believe, never did believe, and never will believe in vaccination." Mr. Kinghorn naively remarked that he thought under the circumstances the young man was hopeless, a remark which excited laughter in court. The magistrate, assuming the young man's objections to be conscientious, and having, as he said, no means of testing his *bona fides*, granted a certificate of exemption. Evidently Mr. Kinghorn felt his position an embarrassing one as regards the means of testing the conscience of the "conscientious objector."

Closing of a Liverpool Cemetery.

The Necropolis, one of the oldest and largest of the remaining intra-mural cemeteries, has been closed under the powers of the Liverpool Improvement Act, 1898, which provides for the acquisition and closing of a number of old burial grounds in the city. The city council has paid £3800 to the proprietors of the cemetery in compensation. A number of small burial grounds have also been closed under the same Act.

The Liverpool School Board and the Scholars' Eyesight.

The Liverpool School Board have arranged for a series of three lectures with demonstrations to be given to head and assistant teachers with regard to the best methods of ascertaining defects in the children's eyesight. The first lecture was delivered on Sept. 5th in the Arts Theatre of University College, Liverpool, by Mr. R. J. Hamilton. The periodical examination of the eyesight of school-children is a step in the right direction and will prove beneficial to them. The board are anxious that the teachers should avail themselves of the opportunity afforded to them by means of these demonstrations.

Charge against a Military Officer of Aiding in Procuring Abortion.

Mr. Sampson, the city coroner, held an inquest on August 29th touching the death of Miss Jane Yates, a young woman, aged twenty-nine years, who died on July 27th under suspicious circumstances. The medical evidence went to show that the patient died from septicæmia the result of a miscarriage. The post-mortem examination revealed evidences of septic peritonitis and a shallow abrasion on the posterior side of the uterus. Mr. F. T. Paul stated that in his opinion the miscarriage was due to the use of one of the catheters produced in court. The jury returned a verdict that Miss Yates's death was caused through procuring abortion and that Lieutenant Wark was privy to the act. As the verdict was equivalent to one of murder Lieutenant Wark was placed under arrest and was committed to the Assizes under the coroner's warrant.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow: Memorial Window in Honour of Principal Caird.

ON the initiative of the Business Committee of the University General Council a movement has been set on foot to place a painted glass window in the Bute Hall of the University as a special tribute by past and present students of the University of Glasgow to the memory of its late distinguished head. The idea is a most appropriate one and has only to be made known to be completely successful. Already many old *alumni* of the University in various parts of the country have sent in contributions. It is estimated that the undertaking will require about £1000 and the maximum subscription is £1 1*s*. As there are many former students of the University whom it is obviously impossible to communicate with from any lists at present available the coöperation of all interested in making the movement known among students of older date is invited. The secretaries are Mr. John G. Kerr, M.A. (Convener of the Business Committee of the University General Council), and the Rev. Arthur Stanley Middleton, M.A. (President of the Students' Representative Council). Mr. Archibald Craig, 156, St. Vincent-street, Glasgow, is treasurer.

Hospitals in Aberdeen.

Intimation having been made by the directors of the Royal Infirmary that they could not see their way to take any more cases of erysipelas into the infirmary the Town Council's Hospital Committee has agreed to admit such cases to the City Hospital, where a ward will be set apart for the purpose. The action of the infirmary directors is probably not unconnected with the fact that for the first seven months of this year there has been a deficit in the finances of £1300. The directors of the infirmary have appealed to the life managers and the public generally for larger subscriptions so as to meet the expenses of the enlarged institution and the increased number of patients. A similar appeal has been issued on behalf of the new convalescent hospital at Pitfodels in the suburbs of the city. For each contribution of one guinea per annum subscribers will have the right to nominate for a week's residence one patient, whether previously treated in the infirmary or not.

Horseplay at the Glasgow Royal Infirmary.

On Wednesday morning last, at the St. Rollox Police-court, Glasgow, ten of the junior staff of the Glasgow Royal Infirmary and two other persons were fined 1 guinea each with the alternative of fourteen days' imprisonment for having ducked another resident in a bath. The cowardice of this combination of twelve persons to do physical violence to one will strike all who hear of the matter. Members of the medical profession who attain to responsible posts in our large hospitals are supposed to have learnt to behave themselves, so that the rough horseplay which these young fellows indulged in was decidedly out of keeping with their positions.

Sept. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever in Strabane.

AT the weekly meeting of the Strabane Board of Guardians, held on August 23rd, it was reported that there were 11 cases of typhoid fever in the Fever Hospital, and 3 other cases were also reported. The Local Government Board have requested Dr. Trimble, medical officer of the Strabane Dispensary District, to let them know the probable source of infection in each case of typhoid fever and scarlet fever which has recently occurred in Strabane.

Nursing in Castleblaney Workhouse.

At an inquest held at the workhouse, Castleblaney, on August 24th, on an inmate of the workhouse infirmary, it was stated in evidence that the deceased was one of about 75 patients in the hospital and infirm wards—24 in hospital, the remainder infirm—who are attended by one nurse and one untrained assistant. These have the care of eight and sometimes of ten wards, and have in addition to the nursing to superintend the washing and serving of food to the inmates of these wards. Dr. Wilson, the medical officer of the workhouse, said in his examination that it was a physical impossibility for the nurse and her assistant to pay proper attention to the sick in the hospital. It appears that the guardians have not carried out the recent requirements of the Local Government Board who called upon them to appoint an efficient staff of nurses to pay proper attention to the sick and infirm. Perhaps the rider added by the jury to their verdict, in which they recommend the Local Government Board to see that an efficient staff of nurses is appointed in the hospital to look after the sick, will have some effect on the guardians.

Bangor District Nursing Society.

At the first annual meeting of this society, held in Bangor on August 23rd, the Marquis of Dufferin presided, and the annual report was submitted by the Marchioness of Dufferin. It would appear that in Bangor trained nursing of the sick poor began on May 24th, the Queen's Birthday, and in commemoration of the Diamond Jubilee. The donations to the society were £89 and the annual subscriptions were £74. The district embraced by the nurse extends for two miles in every direction from the centre of Bangor and her nursing is entirely unsectarian. She had looked after 144 cases during the year and paid 3017 visits. The noble chairman intimated that during the coming year he would deliver a lecture on behalf of the funds of the society.

Belfast Water-supply.

The Belfast Water Commissioners, recognising the vast and increasing population of Belfast, are pushing on their new scheme by which they propose, at a cost of £850,000, to bring the water from the Silent Valley—a huge table-land immediately over Kilkeel, co. Down—a distance of 45 miles. Recently the Commissioners spent two days in inspecting the entire length of route. They first visited the service reservoir situated about five miles from Belfast, near Knockbracken, and found it in a wonderfully forward condition; it is to cost £34,000. They then inspected the conduit from the reservoir to Ballynahinch. It includes a considerable amount of "cut-and-cover" and a tunnel of more than 3¼ miles. This is almost finished and this contract is for £145,000. The next part of the conduit is principally "cut-and-cover" and will cost £45,000. The Commissioners then visited what is a very difficult part of the work, as it includes in addition to 2 miles of "cut and cover" the very laborious task of boring a tunnel 2¼ miles long through the highest of the Mourne range of mountains, Slieve Donard, as well as 7¼ miles of cast-iron and steel syphon pipes. The contract for this is £96,000. On the far side of Slieve Donard, that is, between it and the Silent Valley, the conduit is principally "cut and cover" and will cost £115,000. The Silent Valley, situated 500 feet above sea level, is a most suitable district for a reservoir and catchment area, but it is not contemplated for the present to build a reservoir here, as the supply of water from two rivers—the Kilkeel and Annalong—will for some years to come be sufficient without a reservoir, and the Commissioners have the right to tap these rivers. The work on this gigantic undertaking will probably not be finished for two more years. Then the citizens will have a never-failing supply of water which experts, after examination, declare to be equal to that of Loch Katrine, which supplies Glasgow.

Report of the President of Queen's College, Cork.

The annual report of the president of Queen's College, Cork, has been issued. It refers to the appointment of a lecturer on Celtic and considers there ought to be a chair for such an important subject, especially as comparative philology is receiving so much attention on the Continent at present. The president makes reference to many subjects concerning the medical school. The new pathological laboratory has been completed and is ready for the summer course of practical pathology. There have been very considerable improvements made in the medical department. A splendid collection of frozen sections of the human body has been obtained from Berlin and will shortly be placed in the dissecting-room. Many of these by a new arrangement will be visible on both sides. An excellent set of the newest kind of diagrams has been procured for the anatomical and physiological departments. Models of the viscera and other parts of the body have also been obtained and will be also placed in glass cases in the dissecting-room.

Digitized by Google

There are already several instructive dissections in the anatomical museum. It is proposed to place these in the dissecting-room with models in cases. When these changes have been made the dissecting-room will be well-furnished according to modern ideas. The president deals tentatively with the education question generally and urges on the Government the desirability of founding a University in Cork. In that connexion he alludes to "the extraordinary and quite exceptional ability of the people of the South of Ireland and particularly of those who inhabit the counties of Cork and Kerry." He directs attention to the very large sums provided by the State in various parts of Germany for the development of the national universities, and suggests that if our Government were to devote the same attention to the fostering of higher education in Ireland this country, like Germany, would rapidly attain a high position side by side with England amongst the commercial nations of Europe.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Pulmonary Streptococcus Infection.

THE meetings of the Academy of Medicine are but sparsely attended at present owing to the holidays, but at the meeting held on August 15th M. Clozier reported a very interesting case of what at first appeared to be acute pulmonary tuberculosis. The illness, however, was due to streptococcus infection and was cured by the use of Marmorek's serum. The patient, a boy aged thirteen years, had previously been in good health and there was nothing of note in either his personal or his family history. After coming in from a bicycle ride in the rain he was seized with shivering, his temperature ran up, and he had a cough. Auscultation revealed small crepitations over the whole of both lungs. The sputa, which were muco-purulent, contained none of Koch's bacilli but plenty of streptococci. His condition became more and more serious despite free stimulation and active revulsive treatment. At last he was given a hypodermic injection of 20 c.c. of antistreptococcic serum followed by an injection of 10 c.c. for the next three days. He continued to get worse and there were heard on auscultation tubular breathing, large bubbling râles and pectoriloquy. The three following days the dose of serum was increased to 20 c.c. Finally, three days later than this a pulmonary abscess lying at about the angle of the scapula emptied itself and all the signs of a cavity became audible. One more injection was given and from that time rapid convalescence ensued.

Agglutination in Tuberculous Serum.

At a recent meeting of the Academy of Sciences, a body whose work is less affected by the dull season than that of the other societies, M. S. Arloing and M. P. Courmont read a paper on the best methods of cultivating the bacillus of tuberculosis so as to obtain the agglutinative reaction in a neat and really convincing manner. The culture medium is beef or veal bouillon peptonised 1 in 100 and glycerinated to a strength of 6 in 100. Plain bouillon does not further the growth of the agglutinative material, whatever be the bacillary strength of the cultures, although agglutination sometimes occurs under such circumstances in a very defective manner. The proportion of glycerine is a percentage of from 2 to 12, but the most convenient proportion for bringing about the agglutinative action is a percentage of from 2 to 8. In a culture glycerinated to 6 or 8 per cent. serum manifests an agglutinative power twice as strong as a culture only glycerinated to 2 per cent. Peptone is also indispensable for a good growth. In a bouillon glycerinated but not peptonised the culture is no richer at the end of ten days than in a peptonised bouillon at the end of three. The bouillon must be sterilised by being heated for as short a space of time as possible to a temperature of 110° C. Homogeneity is obtained by frequently shaking the cultures, which are made for this purpose in cylindrical flat-bottomed flasks. Rich cultures of from eight to ten days old are the best for obtaining the agglutinative reaction. In many cultures the agglutinative substance is found to increase up to the fifteenth day, but after that date it diminishes or gets weaker. It is best to work with weak serums and cultures.

Radiography and the Physiology of the Heart.

M. Bouchard at a recent meeting of the Academy of Sciences reported some observations he had made upon the thoracic organs by means of the x rays. Amongst other things he has been enabled to assert the existence of a marked dilatation of the auricles when the intra-thoracic blood-pressure is raised during inspiration. This condition is artificially brought about by endeavouring to inspire with the glottis shut and is naturally brought about by the violent inspirations during a paroxysm of whooping-cough. M. Bouchard has also discovered that a clear horizontal space exists during forced inspiration between the shadow of the heart and that of the diaphragm, but during normal inspiration there is no space visible. This phenomenon, which is remarkable considering that the diaphragm and the pericardium are attached to one another, is explained by M. Bouchard in the following way. During the forced descent of the diaphragm in a large inspiration the inferior surface of the heart is in contact with the diaphragm to a very limited extent. The pericardium tucks itself into the space existing between itself and the heart, forming in front and behind a gutter into which in turn the pulmonary tissue is packed, thus forming a layer of tissue much more penetrable by the x rays than those which make up the heart and the diaphragm.

Vaccination in France.

At the Congress held at Nantes M. Brouardel proposed a resolution, which was unanimously adopted, to the effect that compulsory vaccination should be extended to Tunis. In France vaccination is enforced by strict regulations which do not meet with any opposition from the public. All persons seeking employment of any kind are required to produce a certificate of vaccination and all soldiers are revaccinated on joining their regiments. The Academy of Medicine also awards every year a considerable number of prizes and medals to the medical practitioners and midwives who have performed the most vaccinations and revaccinations. In fact, vaccination is taken quite as a matter of course in France and the arrangements for making it compulsory in the colonies are at the present time almost complete. Under these circumstances no one looked for a campaign against vaccination undertaken by the celebrated anti-Jewish journalist Edouard Drumont, a campaign undertaken in the name of individual liberty and, which is still more strange, in the name of hygiene as understood by M. Drumont. In an article which has produced some sensation and caused astonishment rather than made converts, he declares that small-pox is not a disease but a natural process, in the course of which the organism spontaneously throws off morbid products which it contained; in his opinion vaccination has no other effect than that of closing the pores of the skin and preventing the escape of the morbid products. According to M. Drumont vaccination is the only cause of racial degeneration and of the increase of new diseases which were formerly unknown; on this ground Jenner must be regarded as a scourge of humanity, although it is admitted that he possessed the merits of being an excellent father and a naturalist who carefully studied the habits of the cuckoo. In conclusion, M. Drumont draws attention to the unpopularity of vaccination in Jenner's own country. It is not very probable that the French public, whether medical or non-medical, will be influenced by these fanciful ideas.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Plague in East Africa.

IN a paper on Bubonic Plague which was read a short time since before the Berlin Society of Public Health Professor Koch said that only a few years ago it seemed as if the disease possessed little more than a historical interest, but the recent epidemics in China and the East Indies have proved that under conditions favourable to its development it remains capable of committing great ravages. The researches of Yersin and Kitasato have shown that plague is a contagious disease produced by bacteria, and it has, moreover, been ascertained that it may be to a great extent spread by rats. It is also known that the disease is endemic in certain districts which from time to time become the starting

Digitized by Google

points of epidemics. For instance, the course of the epidemics which came from the East to Europe could be traced back to Mesopotamia and there were grounds for believing that there really was a centre there. The second point of origin is in Central Asia and the epidemics in China and India have obviously had their source there. A third centre of minor importance is situated in Assir, Western Arabia. To these three centres there must now be added a fourth which has not long been recognised. Professor Koch when in Dar-es-Salaam in German East Africa was informed that a disease was prevalent in the Kisiba district the symtoms of which were very like those of bubonic plague. He accordingly sent Dr. Zupitza, one of the colonial medical officers, to this district with instructions to make bacteriological examinations of the cases. Dr. Zupitza's report was to the effect that the clinical symptoms were those of bubonic plague and that the typical bacilli were present in the lymphatic glands and in the spleen. The disease is termed *rubwunga* by the natives, who, moreover, are aware that its germs are spread by rats, and abandon their dwellings as soon as the rats begin to die. Dr Zupitza succeeded in ascertaining the presence of bacilli in three rats. Kisiba, however, is not the real focus of the plague, for the disease was imported eight years ago from the British territory of Uganda, where the *rubwunga* has been known from time immemorial. From Kisiba the disease was carried north to Emin Pasha's provinces and to Upper Egypt. In the beginning of this century there were some small epidemics in Egypt and in the year 1870 there was one in Morocco, the origin of all of which was quite obscure, but it is now known that they were caused by caravans of slaves which had passed through the infected territory. There has hitherto been hardly any traffic between Uganda and the coast of East Africa, but when the railway from Mombassa to that country is finished this state of things will probably be altered and the permanently infected district will be brought into direct communication with the coast. There is no need for alarm on this account, for it is known from the history of plague that the disease has always retired before advancing civilisation. It may therefore be hoped that the spread of civilisation will in course of time have the effect of abolishing plague.

Professor Koch's Investigations on Malaria.

To continue his researches on malaria Professor Koch has gone to Italy accompanied by several of his assistants. The Italian Government has placed the university laboratories at his disposal and will do everything to facilitate his work. On leaving Italy he will proceed to Greece. This first journey will be of a preliminary character and will be finished within three months. Afterwards he will visit the fever districts in East Africa, India, and New Guinea and will be absent there for about two years. The expenses of the expedition will be defrayed by the German Government. Colonial medical officers before going to the tropics will attend courses of instruction at the Institute for Infectious Diseases in order to be trained in the diagnosis and treatment of tropical diseases under the special supervision of Professor Koch and his assistants.

Tuberculosis of the Kidney.

In a paper read before the Berlin Surgical Society and published in the *Deutsche Medicinische Wochenschrift* Professor Israel stated that primary tuberculosis of the kidneys is more frequent than is generally believed. In 21 cases of tuberculosis of the kidneys operated on by him there were 16 cases of primary tuberculosis, the urethra and the bladder being free from the disease. Women are more liable to be affected than men. Both kidneys were attacked in two instances, not including the acute form, which, of course, is only a symptom of acute general tuberculosis and is thus not amenable to surgical treatment. There are three different forms: the most frequent is the cavernous, originating in a caseous degeneration and usually combined with suppuration of the adipose capsule. The second form has its seat in the papilla; it is very rare and is characterised by profuse hæmaturia. The third form is the nodose condition, in which the whole kidney is occupied by numerous nodules of different sizes. Secondary tuberculosis of the bladder was observed in 43 per cent. of the cases operated on; this complication was therefore not regarded as contra-indicating operation. It is very important to ascertain the state of the patient's second kidney. In 14·3 per cent. of the cases operated on both kidneys were affected. Professor Israel is of opinion that when tuberculosis of the kidneys is combined with tuberculosis of the bladder and the genital organs both conditions originate in infection by the blood; in support of this view he mentions a case where tuberculosis of the kidneys was combined with tuberculosis of the testicle whilst the bladder remained healthy. The affection of the kidneys may be the only symptom of general tuberculosis, but on making a post-mortem examination tuberculosis of the lungs was discovered in about 50 per cent. of the cases. The patients, however, did not look like tuberculous subjects; there were among them men whose weight was 100 kilos. (220 lb.). Hæmaturia is the most important clinical symptom and in 4 out of 16 cases it was the only trouble present at the outset. Enlargement of the kidney could be ascertained by palpation in nearly all instances. Koch's bacilli were seldom found in the urine when the bladder was free from disease, but they are present in the great majority of cases of tuberculosis of the bladder. The bacilli thus, as a rule, come from the bladder and not from the kidney. The following complications were observed: perinephritic abscess, tuberculosis of the adipose capsule, tuberculous pleuritis and fistula of the colon. Fever was present in only 25 per cent. of the cases, but in tuberculosis of the bladder in 80 per cent. 21 patients were operated on and in all cases but 1 the kidney was entirely removed. 3 patients died as a result of the operation, either from shock or from affection of the second kidney; 5 died from tuberculosis after the wound had nearly healed. Of the cases with healthy bladder 6 are still alive, 1 of whom was operated on nine years ago. In the cases complicated by affection of the bladder there was obvious amelioration of the symptoms and sometimes, also, a partial healing could be recognised by examination with the cystoscope. Professor Israel concludes that in primary tuberculosis of the kidneys, either with or without implication of the bladder, an early operation is necessary; in secondary ascending tuberculosis operation should only be performed when grave symptoms have arisen or when the patient's general health is obviously suffering. Extirpation of the kidney should be the usual operation; simple nephrotomy is allowable only when both kidneys are involved and where fever caused by retention of pus makes an operation necessary.

Sept. 5th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch's Study of Malaria.

WITH the facilities afforded him by the Premier, General Pelloux, and the coöperation of his old friend Guido Baccelli, once more Minister of Public Instruction, Professor Koch pursues his researches into the bacillus malariæ and its pathological effects with every official aid and encouragement desirable. Indeed, he has only to indicate the direction in which he wants to widen or deepen his investigations and the Government responds with sympathetic alacrity. The other day he expressed a wish to examine a number of cases of malaria perniciosa as at present prevailing in certain military hospitals and the Direzione Generale di Sanità, through the Minister of War, at once procured the opportunity required. In fact, Colonel Panara, Medical Inspector of Hospitals, was deputed by the War Office to place himself at Professor Koch's disposal till his purpose is fully carried out. The thoroughness with which the great bacteriologist is conducting his researches is eminently characteristic. Fresh from the Dark Continent, where he began his present study of malaria, and *en route* from Germany, he had barely alighted on Italian soil when he made a halt at Milan and, accompanied by his two assistants, Dr. Pfeiffer and Dr. Kossel, examined the more typical cases of the fever in the Spedale Maggiore, whence he carried away with him specimens of the malaria-infected blood. He did likewise at Pavia, and on his way to Rome made a brief stay at Florence, where he was met by Baccelli, and lost no time in availing himself of the clinical opportunities afforded by that school. His sojourn in the Eternal City will be prolonged till the third week in September or even later, and I believe he will extend the area of his researches so as to include the Neapolitan Riviera before completing the study to which the medical

Digitized by Google

world is now looking for fresh light on one of the most obscure, while most widely prevalent, of maladies. Since his arrival at Rome Professor Koch has followed up the quest he started a year ago in Southern and Central Africa, and ably assisted by Dr. Pfeiffer and Dr. Kossel of Berlin and by Professor Bartolommeo Gozio (bacteriologist of the Public Health Department and pupil of his own in the same school), works daily in the fever wards and *gabinetto della clinica* of the Santo Spirito Hospital, both placed at his disposal by Government for as long as he sees fit to use them. From half past six in the morning till noon the four men divide their labour and time between the bedsides of the patients and the laboratory; at 3 P.M. they resume operations; and only at 6 o'clock, or sometimes later, do they suspend them till the morrow. Professor Koch has twenty typical cases under his eye for clinical observation and bacteriological analysis, but he makes a point of seeing every fresh patient on admission, always with a view to symptoms or phenomena either novel or more pronounced. Not only so, but on certain days he proceeds to such *foci malariæ* in the neighbourhood as the Trappist monastery of the Tre Fontani (the scene of St. Paul's martyrdom); and on others he goes further afield—to Ostia, at the mouth of the Tiber, to Maccarese, and even to the Pontine Marshes. These excursions he makes for etiological purposes, so as to study the genesis of the fever, or at least the conditions under which it is intensified, if not actually evolved. On this side of the subject he expressed himself to the Commendatore Santoliquido, of the Public Health Department, as materially indebted to the Italian investigators, from Lancisi early in last century, down to Tommasi-Crudeli and his successors, whose work dates from 1878 onwards. I may add that he seldom misses a necropsy, particularly if the dead subject has had the disease in its *forma perniciosa*. No opportunity, in fact, escapes him of adding to the material necessary whether in the clinical or in the bacteriological field, and, as I have already stated, his experience at the Spedale dello Santo Spirito will be supplemented by a series of visits to the hospitals of the Roman garrison, in which, especially at this season, typical cases of the fever in its various forms are always to be found.

The University of Cambridge and Professor Golgi.

While on the subject of malaria I may mention the genuine gratification of the profession in Italy at the honour just bestowed by the University of Cambridge on one of the most meritorious workers in that field. Professor Camillo Golgi received not only from the Pro-Rector and his colleagues in the University of Pavia their cordial congratulations on the high distinction awarded him, but the mayor of the town, in name of the Giunta and the citizens, sent him similar felicitations on the event. The happy epigram in which Dr. Sandys, the Public Orator, conveyed the honour has already gone the round of the Italian press. "The death of Camillus by malaria has been avenged by a second Camillus" (*Camilli mortem pestilentia absumpti Camillus alter ultus est!*). Academic Italy has not forgotten how, on the occasion of the centenary celebrations of Bologna and Padua in 1888 and 1892 respectively, Cambridge far outshone her European sisters in the classic elegance, both in verse and prose, in which she couched her congratulations to either University, and she is glad, amid the controversies now raging as to the retention or modification of her time-honoured faculties, to cite the example of the English seat of learning where science, pure and applied, and literature, ancient and modern, are cultivated side by side without prejudice to either, but rather to the reciprocal advantage of both.

The Heat.

We are now emerging from a period of high temperature rarely experienced even in a Roman August. It was fondly hoped that this year's summer months would have been moderate as to heat, considering the extraordinary rainfall of June and July; but from August 15th the thermometer rose steadily, reaching on that day a maximum of 32·2° C., and steadily mounting still higher, particularly in the Alta Italia, where at Milan, Pavia, Brescia, Cremona, and other meteorological stations, a temperature truly tropical was registered. "It is difficult," says Signor Pio Bettoni, the able director of the observatory at Salò, "to explain this phenomenon. We cannot, in my judgment, accept the hypothesis that these excessive heat-waves are due to the state of eruptive activity of the *superficie solare* and other cosmic conditions. I greatly doubt whether more value can be ascribed to those 'variations of climate,' according to the theory of Brückner, received with such favour by some meteorologists who hold them to be *fenomeni meteorici* subjected to a periodicity of thirty-five years. I hazard no opinion of my own, but I invite attention to a fact. When during the day the sky has been notably clear, with a prolonged solar illumination, as we have lately experienced, and when during the night it has been cloudy or starless, we invariably have at this season a marked recrudescence of heat."

Sept. 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Medical Practitioners in Austria.

THE number of medical practitioners in Lower Austria has increased from 1936 in 1889 to 2593 in 1896, in Bohemia from 1629 in 1889 to 2131 in 1896, and in Galicia from 860 in 1889 to 1221 in 1896. Those who have passed away included 588 surgeons of the old school (*Wundärzte*), and 2544 young graduates have entered on a medical career. In 1889 there were 248 places without any medical practitioner, but in 1896 the number was 9 per cent. less.

Stypticin.

Dr. Braitenberg has published an interesting report on the use of stypticin in uterine hæmorrhages, especially those which are due to perimetritis, parametritis, inflammation of the adnexa, or profuse and protracted menstruation. Stypticin forms a yellow crystalline powder and is the hydrochloric acid compound of cotarnine, a base which is obtained from narcotine, one of the opium alkaloids. It may be given in doses of 0·05 gramme (¾ grain); in urgent cases the dose may be increased to 0·1 gramme or 0·2 gramme (1½ grain or 3 grains) injected into the gluteal region.

The Retort of an Unqualified Practitioner.

A patient who had lost confidence in ordinary medical treatment sent to an unqualified practitioner for a supply of Alpine moss, the curative powers of which were highly vaunted. At different times eight parcels of moss were sent to him, each costing 20 gulden (about £1 15*s.*), but it proved to be useless, and in reply to a threat that he would take legal proceedings he received a letter to the effect that if the moss had not done good to him it had at any rate done good to the sender, who made a livelihood out of people with plenty of money. The patient was also informed that if he used the moss for stopping up the chinks of his windows in autumn he would be protected from draughts and would feel less pain.

Treatment of Chronic Arthritis.

A recent number of the *Medicinische Presse* contained an article by Dr. Bier on the treatment of chronic arthritis by active hyperæmia, and engorgement. In 1891 he tried the experiment of treating tuberculous diseases of the joints with hot air applied so as to produce artificial hyperæmia, and he afterwards used this method in chronic arthritis, but in the latter case he found engorgement more effectual, for the hyperæmia produced by engorgement is more marked and lasts longer than that obtained with hot air. When engorgement is to be employed the leg is enveloped in a cambric bandage reaching from the toes to the knee for the purpose of preventing engorgement of the blood in healthy parts, and an indiarubber bandage is then applied over the knee-joint, so that it becomes cyanotic. The bandage must remain constantly in position until the pain has disappeared.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The American Medical Association and the Requirements for the Degree in Medicine.

THE American Medical Association in 1892 unanimously resolved to demand of all the medical colleges of the United States the adoption and observance of a standard of requirements of all candidates for the degree of Doctor of Medicine

Digitized by Google

which should in no manner fall below the minimum standard of the Association of American Medical Colleges, and this demand was sent officially by the permanent secretary to the dean of every medical college in the United States. Now the association gives notice that hereafter no professor or teacher in, or any graduate of, any medical college in the United States which shall after Jan. 1st, 1899, confer the degree of Doctor of Medicine or receive such degree on any conditions below the published standard of the Association of American Medical Colleges will be allowed to register as either delegate or permanent member of this association.

The Nursing Bottle Ordinance.

The Health Department of the city of Buffalo enacted the following ordinance in 1890: "It shall be unlawful for any person or persons to use or engage in the sale of any bottle, mechanism, or other device for the artificial feeding or nursing of infants or children under three years of age that has connected therewith a rubber tube, hose, or similar contrivance." The object of this ordinance was to banish from the market the long-tube nursing bottle. Five convictions have since been secured by the Health Department and suits have been commenced against thirty other dealers. Vigorous opposition to the ordinance is being made in the courts, but the Department is sustained by the County Medical Society, which recently issued the following statement: "The death-rate among the artificially-fed newly-born marks the level of the sanitary enlightenment of the community. Competent medical opinion has, and does, unhesitatingly and unanimously condemn a certain type of feeding bottles in frequent use. Inspired by such well-founded conviction ordinances forbidding the sale of this apparatus were recently enacted by the proper authorities of this city. The relations between the professions of medicine and pharmacy are, and should be, most reciprocal and harmonious, the pharmacist being a conspicuous citizen, learned in medicine, with singular opportunities to form and develop a right public opinion. We commend to the druggists and pharmacists of our city, our health ordinances in general, and with greater particularity the ordinance forbidding the sale of a certain class of feeding-bottles, as timely, wise, and in the best interests of the public health; and we invite them to join us in supporting these ordinances with their earnest and constant efforts. We commend to all those in authority the subject of the preservation of the lives of the newly-born and those of tender years as of the highest practical importance and deserving their incessant and sleepless vigilance. We approve, in the most hearty and unqualified terms, of the ordinance prohibiting the sale of any nursing-bottle which has connected therewith a rubber tube, hose, or similar contrivance."

Precautions against Yellow Fever.

Precautions are being taken by both the War and Treasury Departments to prevent the introduction of yellow fever into the United States. The officials of these two departments are coöperating very thoroughly in the efforts which are being made and the opinion of those best informed is that they will be successful. The Secretary of War has issued the following instructions:—1. That medical officers of the United States Marine Hospital Service be immediately detailed for duty at Santiago, and subsequently at other Cuban or Porto Rican ports under control of United States forces, to carry out the requirements of the Quarantine laws of 1883, such officers to issue certificates and perform other duties of sanitary or other port inspectors. 2. That all sanitary matters pertaining to the condition of transports and crews be placed under the jurisdiction of the medical officers of the Marine Hospital Service of the United States. Every vessel engaged in the transport service between the United States and Cuban or Porto Rican ports to carry a medical officer of the Army or of the Marine Hospital Service, whose duty shall be that of sanitary inspector of the vessel, and who shall see that in a foreign port no material or person is taken aboard liable to convey yellow fever, to keep the crews of the transports under surveillance, and on the return voyage to act as sanitary inspector. 3. That there be placed at Santiago and every chief port where practicable a receiving ship for the recreation of those who take passage for ports in the United States. This ship would be practically a detention camp and quarantine station and passengers seeking homeward voyage would be taken from this vessel after they had undergone a period of observation and disinfection of their effects.

A Steam Vessel Equipped for Disinfection.

The *Protector*, the first vessel in the world to be equipped solely for the purpose of disinfection, is about 80 ft. long. On deck is a structure fitted for bathrooms. It is intended that soldiers shall come on board, take a bath, and give up their clothing, receiving new clothes in exchange. The old clothing will then be taken below, thoroughly sterilised, and then returned to the owner. In the bow of the boat are a sulphur furnace, combustion chambers, and a fan for disinfecting vessels. In the middle are a sterilising chamber and a formaldehyde generator. A boiler and a water-heater are near the stern. The sulphur furnace will be used for disinfecting vessels. The hatches of the vessel to be treated will be battened down and piping carried from the *Protector* to the hold of the vessel. Through this tubing sulphur fumes will be pumped by the fan in the *Protector*. Air is drawn into and through the sulphur furnace, baffle-plates being so placed as to thoroughly mix air and sulphur fumes, a fairly perfect combustion being thus obtained. The sterilising apparatus consists of a cylinder, a chamber, and an exhauster. The chamber is of iron and though open at both ends it can be hermetically sealed. The exhauster consists of a steam-jet for removing air from the chamber. The generator is a copper cylinder divided vertically into two parts, a steam coil being placed in each part. The clothes to be sterilised are placed in the chamber, the air in which is removed by means of the steam-jet exhauster. Formaline is placed in part of the generator and steam admitted to the coil, and when sufficient heat has been thus applied to generate the required amount of formaldehyde gas the gas is admitted to the chamber. At the end of half an hour ammonia placed in the other part of the generator and similarly heated is admitted to the chamber. This neutralises the formaldehyde and the clothes are removed and returned to the owners.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Measles in Victoria.

MEASLES made its appearance in epidemic form in Victoria in December last. The outbreak appears to have reached its greatest severity in April and to be now abating. During the whole period 341 persons, chiefly children, have died from the disease. The Board of Health has directed an inquiry to be made by its assistant medical officer into the circumstances associated with the fatal cases. It is believed that while the epidemic has been most impartial in its attacks the fatal cases have occurred almost entirely among those in poor circumstances, and it is thought that in future epidemics the mortality might possibly be diminished by a wider dissemination of information and an extension of the system of district nursing. During the last 25 years six epidemics of measles have occurred, of which that in 1874–75 was the most fatal, causing 733 deaths, and that in 1893 was next in fatality, causing 386 deaths. The epidemics have recurred every 4 or 5 years with considerable regularity but apparently uninfluenced by season.

The Water-supply of Bendigo.

In March last the health officer at Bendigo in reporting on a recent outbreak of typhoid fever in that city attributed it to pollution of the water-supply. The analytical chemist for water-supply has made an examination of the locality and a careful chemical and bacteriological examination of various samples of the water from both the reservoir and the mains. In no case was the typhoid bacillus found or the bacillus coli communis. While the failure to find bacilli did not prove that the outbreak was not due to the water-supply his investigations did not bear out the health officer's statements and it was not proved that the outbreak was due to the water-supply. Nevertheless, the water-supply was not good and was liable to pollution in the reticulation area. He recommends a system of house filtration under official control, for which an efficient filter is now available at a cheap rate.

Melbourne Fever Hospital.

The Premier of Victoria has officially notified the Heidelberg Municipal Council that it had been finally decided to grant fifteen acres of the reserve at the Yarra Bend

Digitized by Google

Lunatic Asylum to the Infectious Diseases Hospital Committee subject to the following conditions: (1) that the site be enclosed by a high iron fence; (2) that no person suffering from small-pox, plague, or other exotic infectious or contagious disease be admitted to the hospital; (3) that no drainage be permitted to pass into the River Yarra or through the asylum reserve (except by underground sewer connected with the Metropolitan Board of Works system) unless on such conditions as may be approved of by the lunacy department, that is, by the chief secretary or inspector of asylums for the insane; (4) that the Government shall have the right to send patients to the hospital; and (5) that any requirements of the Minister of Health as to dealing with infectious matter and passing the air from the wards through fire shall be complied with.

The Public Charities in Victoria.

The report of the inspector of charitable institutions in Victoria has just been laid before Parliament. The accommodation provided and the number of inmates at the various institutions were as follows:—

	Beds provided.	Inmates.
Hospitals	2253	1716
Hospitals and benevolent asylums	667	555
Benevolent asylums	2350	2314
Orphanages	983	884
Asylums (blind, deaf and dumb, and infant)	255	225
Refuges	524	526
Convalescent homes	63	29
	7095	6249

The number of persons receiving charitable relief for the year is estimated at 99,277, of whom 71,698 received outdoor relief. The chief sources of income, irrespectively of the Government grant of £100,000, were:—

Municipal grant	£8,022
Locally raised contributions	79,533
Interest upon investments	9,738
Paying patients and paying pupils	7,754
Out-patients' fees	3,616
Proceeds of inmates' labour	9,407
Legacies and bequests	4,149
Other sources	11,476
	£133,695

The cost per bed per annum for the daily average of patients varied a good deal in the leading hospitals and on the whole was considerably higher than in similar institutions in Great Britain. Thus the cost at the Melbourne Hospital was £75 12*s.* 9*d.*; at the Alfred Hospital, Melbourne, £70 11*s.* 8*d.*; at the Women's Hospital, Melbourne, £74 13*s.* 3*d.*; at Ballarat Hospital, £52 7*s.* 9*d.*; and at Bendigo Hospital, £49 14*s.* 7*d.* The inspector advocates the establishment of a Nurses' Fund for sickness and superannuation and a half-yearly inspection and test of the efficiency of the fire-appliances of each institution. He expresses fear that serious loss of life would occur in the event of an outbreak of fire at any of the hospitals or asylums, since in none that he had visited did the employés know their stations in case of such emergency. At the annual meeting of the Charity Organisation Society the President (Professor Morris) said the work of the society was of two kinds, registration and inquiry into individual cases and the organisation of charity. The case work had now been so well done that when a subscriber sought information it could generally be given at once, as in the books of the society were to be found particulars of 11,000 cases. The organisation of charity, however, was not so satisfactory and must be taken in hand by the Government. The great need of the charities was not more money but better organisation and administration. Many of the hospitals had a large number of what were really benevolent asylum inmates, maintained in the hospitals at expensive rates. Victoria was quite sufficiently supplied with hospitals; in fact, the Government should provide measures to prevent the creation of unnecessary hospitals, but was lamentably deficient in benevolent asylums. Professor Morris also criticised very adversely the methods of electing the medical staffs at some of the hospitals by the votes of the subscribers.

Deaths at the Melbourne Benevolent Asylum.

An article appeared recently in the *Melbourne Argus* stating that 600 deaths had occurred in three years at the Melbourne Benevolent Asylum and no inquest had been held at the institution since the year 1891. The secretary to the asylum reported that the actual number of deaths in the last three years was 450 and it was pointed out that it was not the fault of the officers of the institution if no inquests were held and that no necessity for holding inquests existed, most of the patients dying from natural causes and the ordinary certificate being given by the medical officer.

Lunatic Asylums in Victoria.

The inspector of hospitals for the insane in Victoria has presented his annual report. He again draws attention to the overcrowding of the metropolitan asylums. The asylum population has increased largely within the last few years and will probably continue to increase, and provision must be made to accommodate the increase. He recommends that the Ballarat Asylum should be enlarged and special provision made at it for epileptics. The removal of all epileptics from the metropolitan asylums would enable a better system of classification to be introduced and better means to be adopted for the treatment of recent and curable cases. Great difficulty has been experienced in obtaining suitable men to fill vacancies on the medical staff owing to the low rate of pay given by the Government. Two vacancies for junior medical officers exist at the present time, but no applications have so far been received. The inspector urges that arrangements should be quickly made which will secure and retain in the service competent officers on whom depends in a great measure the satisfactory working of the asylums. The inspector also complains of the low rate of pay of some of the nurses and attendants, which causes many changes in the staff by resignations and transfers to other departments.

A Medical Man committed for Manslaughter.

On July 4th at the coroner's court, Sydney, Dr. Terence Albert Green was committed to take his trial for the manslaughter of Pauline Durlac. The circumstances of the case are of considerable medical interest. Dr. Green was first consulted by Miss Durlac about four months before her death for injuries received to her leg in an accident. After her recovery she was treated for some uterine condition, which, he said in evidence, he diagnosed as chronic enlargement of the uterus and endometritis. He advised curettage, and first to have a consultation with Dr. Worrall. The patient declined the consultation but decided to have the operation performed. Dr. Martin administered chloroform and after the operation was commenced Dr. Green discovered that the patient was pregnant. He then cleared out the uterus. Severe hæmorrhage followed and the patient died. Dr. Green, after a conversation with Dr. Martin as to reporting the death to the coroner, gave a certificate that death was due to endometritis and hæmorrhage. The police were subsequently informed and the body was exhumed. Dr. Rennie and Dr. Taylor made a post-mortem examination and found a rupture in the uterus and stated in evidence that the cause of death was rupture and hæmorrhage, that the breast contained milk, and that it ought to have been quite possible to have diagnosed that deceased was pregnant during life. The coroner, in summing up, said that from the evidence it appeared that Dr. Green did not visit the patient with intent to commit a criminal act. The jury had to consider, however, whether culpable negligence had not been shown in not ascertaining the patient's condition before operating and whether there was not carelessness in the performance of the operation itself, and to consider the fact that the actual conditions had been concealed and a wrong certificate given. The jury found that the deceased died from hæmorrhage consequent upon an operation performed by Dr. Green, who did not exercise the necessary precautions to ascertain her condition. The coroner said that that was equivalent to a verdict of manslaughter, to which the jury assented.

The Coast Hospital, Little Bay, Sydney.

The report of the chief medical officer of the Government on the Coast Hospital, Sydney, has been presented to Parliament. The institution is used as a hospital for infectious and typhoid fevers and as a hospital for chronic cases and for convalescents. A moderate number of out-patients from the neighbourhood had been treated and surgical cases had gradually been admitted. The total number of cases treated had increased from 1132 in 1884 to 2307 in 1897, and the average daily number of in-patients from 104 to 224. An increase in the medical staff was recommended.

The Financial Position of the Melbourne Hospital.

The annual report of the Committee of Management of the Melbourne Hospital shows a deficiency of revenue of over

Digitized by Google

£5000 for the year. The cost of maintenance has been increased by the advance in the prices of supplies and the extra nursing required by the prevalence of epidemic disease. The total expenditure was £25,953, an increase on the previous year of £1551. The total receipts amounted to £20,645. A special committee has been appointed to investigate the expenditure and devise means of increasing the income. One means suggested is to endeavour to get contributions from in-patients. This plan has been adopted at the Alfred Hospital, Melbourne, with very satisfactory results. The strain upon the resources of the Melbourne Hospital is shown by the fact that 340 patients had to be refused admission for want of room. In the wards for infectious cases alone 613 patients had been treated, 264 of which were cases of diphtheria, and the high price of antitoxin, which had been freely used, was an item in swelling the expenditure.

Death of a Centenarian.

On July 22nd Mrs. John Beirs died at Adelaide at the age of 102 years. She arrived in the colony in 1838, and had been bedridden for ten years.

July 31st.

Obituary.

GEORGE ROPER, M.D. ABERD., M.R.C.P. LOND., M.R.C.S. ENG.

DR. ROPER belonged to a family which had lived at Colby in Norfolk for about three hundred years. He was the third son of Mr. Snelling Drosier Roper and was born at Colby on August 15th, 1823. He received his medical education at Guy's Hospital and became a Member of the Royal College of Surgeons of England and a Licentiate of the Apothecaries' Society in 1847. After a voyage in one of the Hudson Bay Company's ships he started in general practice in the prolific centre of Shoreditch, joining Mr. F. Wildbore as assistant and later succeeding him as chief. His work was arduous and he acquired a good reputation in the East-end, in particular as a scientific and successful obstetrician. Fortune favoured him in that he received substantial legacies which made him independent. He gave up general practice, went to Aberdeen for a year, where he took the degree of M.D. in 1873, and became a Member of the Royal College of Physicians of London in 1874. He settled for a time in Finsbury-circus and was elected physician to the Royal Maternity Charity for the Eastern Division. During four years he did good work in that capacity and he summed up his experience in a memoir on "The Use of the Forceps and its Alternatives" which was printed in the *Transactions of the Obstetrical Society of London* in 1879. He also contributed a paper on the Action of the Ileo-cæcal Valve in Stercoraceous Vomiting to the *Medical Gazette* in 1849, an account of a Case of Sudden Death during Labour to THE LANCET in 1855, and a paper on Cases of Hypertrophic Elongation of the Cervix Uteri in Labour at Full Term to the *Transactions of the Obstetrical Society of London*. Having been elected physician to the Royal Hospital for Children and Women, Waterloo-road, he removed to Ovington-square and had at the same time consulting-rooms near Cavendish-square. But after a short time he left London and settled at Oulton, near his native place in Norfolk, where he lived for some years. He never married, and failing in health he gave up his house and went to live with some relatives at Southwold in Suffolk, where he died on August 14th, 1898, at the age of seventy-five years. He was a vice-president of the Obstetrical Society of London and of the Hunterian Society, a Fellow of the Royal Medical and Chirurgical Society, and a Corresponding Member of the Gynæcological Society of Boston. Dr. Roper was a good judge of horses and an ardent lover of sport of all kinds—shooting, coursing, racing, and salmon fishing. He had also travelled much. As we have already said, on becoming qualified he went to Hudson's Bay as surgeon on one of the Company's vessels; in 1867 he went to China, Japan, Canada, and the United States; in 1881 he spent many months in Holland, the south of France, Italy, and Spain; and in 1886 and 1887 he travelled for eighteen months in Canada and the United States.

Sir Samuel Wilks writes as follows concerning Dr. George Roper, whom he knew intimately: "No man have I more respected than Dr. George Roper. Knowing him first as a fellow student and then through a long life, my estimate of him, both professionally and personally, has been of the highest. I remember Dr. Roper in general practice in the East-end of London, and it was a large and remunerative one. I often spoke to him of his choice of locality in a low-class neighbourhood, and he answered me quite characteristically that he would rather earn a guinea by seeing a dozen poor people over whom he had influence than by spending the time in talking over the imaginary grievances of some ancient dowager. Straightforwardness and independence of character were his main qualities. He told me that he had never quarrelled with a brother practitioner but had had some severe differences with more than one leading man in the profession owing to his belief that he had been unfairly dealt with in consultation. He was not the man to accept an insult, and just and generous as he was to others he conceived that they should act in the same manner towards himself. He was remarkably acute in his insight into cases and with a good knowledge of his profession he made some capital diagnoses in cases of difficulty. He took a great interest in and paid especial attention to operative midwifery. In middle life he determined to give up general practice and to devote himself to his favourite specialty as a consultant. Having no degree he proceeded to Aberdeen and nothing better than this determination to do so showed Dr. Roper's indomitable perseverance. He entered the classes and examinations like other and younger students, where his ardour was so marked that he became known as 'young Roper.' After he took his degree he became a Member of the Royal College of Physicians of London and attached himself to the Infirmary for Women and Children in the Waterloo-road, where he had an opportunity of practically applying his knowledge of female diseases with great benefit to the institution. He was a diligent member of the Obstetrical Society and a most valuable officer of the Maternity Charity."

From Sir Samuel Wilks's sympathetic little note, as well as from the facts of Dr. Roper's life which we have briefly given, it will be clear that he belonged to an order of practitioners whose members can be ill spared by the profession or the public. He combined a love of science and a grasp of its principles with a delight in the practical side of his work, and he was above all things anxious to be the friend of his patients and to do them good in all ways. Dr. Roper had suffered severely from angina pectoris for several years before his death, which, in the end, occurred somewhat suddenly.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Evert Julius Bonsdorff, formerly Professor of Anatomy and Physiology in the University of Helsingfors.—Dr. H. Endres, *privat-docent* of Anatomy and Histology in the University of Halle.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Vienna:* Dr. Arthur Schattenfroh has been recognised as *privat-docent* of Hygiene.—*Berlin:* Dr. Georg Puppe has been recognised as *privat-docent* of Forensic Medicine.—*Budapest:* Dr. Géza Krepuska has been recognised as *privat-docent* of Otology, Dr. Karl Morelli as *privat-docent* of Laryngology and Rhinology, and Dr. Desider Kuthy as *privat-docent* of Hydrotherapy and Climatology.—*Bologna:* Dr. Umberto Monari of Turin has been recognised as *privat-docent* of Surgery.—*Cincinnati (Ohio Medical College):* Dr. C. L. Bonifield has been appointed Professor of Clinical Gynæcology and Dr. S. C. Ayres Professor of Ophthalmology.—*Cracow:* Dr. Wladimir Sieradzki has been recognised as *privat-docent* of Forensic Medicine.—*Modena:* Dr. Giulio Vassale has been promoted to the chair of General Pathology.—*Naples:* Dr. Gaetano Sorge has been recognised as *privat-docent* of Operative Medicine.—*Prague (Bohemian University):* Dr. Alois Velich has been recognised as *privat-docent* of General and Experimental Pathology, Dr. Karl

Digitized by Google

Svehla as *privat-docent* of Pædiatrics, and Dr. Ivan Honl as *privat-docent* of Bacteriology.

A STRANGE OBJECTION TO CALF LYMPH.—At the meeting of the Chard (Somerset) Board of Guardians held on Aug. 22nd a member mentioned a rumour that children vaccinated with calf lymph were in the habit of "blaring" at night.

AN UNREGISTERED DENTIST.—At the Pontypridd Petty Sessions held on Aug. 24th a man named Charles was fined £5 for practising as a dentist without being registered under the Dentists Act. The evidence showed that the defendant possessed the D.D.S. of America.

THE LATE MR. AUGUSTIN PRICHARD.—The family of the late Mr. Augustin Prichard, F.R.C.S., of Bristol, have presented to the Bristol Museum the valuable collection of human crania brought together by the distinguished ethnologist Dr. James Cowles Prichard and his son, the late Mr. Augustin Prichard.

THE DOWAGER LADY HOWARD DE WALDEN has presented a site for a nurses' home and club in connexion with the Nurses' Coöperation (of which H.R.H. Princess Louise, Marchioness of Lorne, is patroness) and has promised to provide a large proportion of the cost of erecting a suitable building.

SOMERSET ARCHÆOLOGICAL SOCIETY.—The fiftieth annual meeting of the Somersetshire Archæological and Natural History Society was held at Taunton recently. In order to celebrate the jubilee by a permanent memorial it was proposed to restore the ancient hall of Taunton Castle, the property of the society, and to convert it into a museum.

AMERICAN CLIMATOLOGICAL ASSOCIATION.—The fifteenth annual meeting of this association was held at the Maplewood Hotel, near Bethlehem, New Hampshire, on August 31st and Sept. 1st, 1898. An opening address was delivered by the President, Dr. E. O. Otis of Boston, who took for his subject Avenbrugger and Laennec, the Discoverers of Auscultation and Percussion.

VACCINATION AT DEVIZES.—At a recent meeting of the Devizes Board of Guardians it was stated that the vaccination returns for the first district of the union, which includes Devizes, showed that during the six months ended Dec. 31st, 1897, there had been 164 births, and that of these children 62 had been successfully vaccinated, 8 had died unvaccinated, 3 had removed, and 91 were unaccounted for.

UNIVERSITY COLLEGE OF WALES.—Sir William Vernon Harcourt will open on Oct. 26th the new portion of the University College of Wales, Aberystwyth, erected at a cost of nearly £20,000. In the evening the Master of Trinity College, Cambridge, will give the inaugural lecture and on the following day the degrees of the Welsh University will be conferred at Aberystwyth.

NATIONAL REGISTRATION OF PLUMBERS.—A public meeting will be held in the Mayor's Parlour, Manchester, on Sept. 19th, at which the Lord Mayor will distribute the prizes, certificates, and bronze medal of the Plumbers' Company awarded in connexion with the recent Exhibition of Plumbers' Work at Manchester. The programme will include a lecture on the Registration of Plumbers and Domestic Sanitation, by Dr. Mansel-Howe.

PRESENTATION TO A MEDICAL MAN.—At a public meeting held at Cwmavon, near Port Talbot, on August 27th, which was presided over by the Mayor of Aberavon, Mr. Robert William Roberts, L.R.C.P. & S. Edin., L.F.P.S. Glasg., was presented with a drawing-room clock with ornaments, dining-room clock with ornaments, etchings, and an ophthalmoscope, as a mark of respect and esteem on the occasion of his marriage.

THE DEATH OF MR. EDWARD CURTICE.—Mr. Edward Curtice, proprietor of the Press Cutting Agency of Romeike and Curtice, passed away on August 30th at his residence in Museum-street, after a long and painful illness. Mr. Curtice, who commenced as a wholesale newsagent and publisher, was the first to recognise the value of Romeike's enterprise in starting some twenty years ago a press-cutting agency which should be a general intelligence bureau.

THE LONDON HOSPITAL.—A quarterly court of the governors of this hospital was held on Sept. 7th, when a promising financial position was revealed. A special appeal was made early in the year for £100,000, of which £77,000 has been received or promised in donations and £11,000 in annual subscriptions. The Press bazaar in aid of the hospital brought in £12,000, while it is understood that the Prince of Wales's Hospital Fund will make a large annual donation conditional upon certain improvements in structure being made. Three new operating theatres are to be built at the cost of £13,000, the expenses being entirely defrayed by an anonymous donor. An annual saving of over £1000 a year is said to have been effected by charging certain of the out-patients 3*d.* for bandages and medicines. This is a departure at the London Hospital and one that will probably attract some attention.

GREG, A. H., B.A. Camb., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

HALL, J. S., L.R.C.P., M.R.C.S., has been appointed Junior Ophthalmic House Surgeon to St. Thomas's Hospital.

HASLAM, H. C., M.A., M.B., B.C. Camb., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

KILVERT, J. E., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

MCCLEAN, J. F., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

MAKINS, G. H., F.R.C.S., has been appointed Consulting Surgeon on the Honorary Medical Staff of the Evelina Hospital for Sick Children.

PIERCE, R. W. C., M.B., B.Sc., Lond., L.R.C.P., M.R.C.S., D.P.H. Camb., has been appointed House Physician to St. Thomas's Hospital.

REVELY, J. S., M.D., M.R.C.S., has been appointed Medical Officer to the Tettenhall District of the Seisdon Union.

ROBINSON, A. C., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

SHEA, H. F., M.B., B.S. Durh., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

SHEARS, CHARLES H. B., Surgeon to the Liverpool Eye and Ear Infirmary, has been appointed Ophthalmic Referee for County Court Circuit 6 under the Workmen's Compensation Act, 1897.

SNELL, E. H., M.D., B.Sc. Lond., D.P.H., M.R.C.S., L.R.C.P., has been re-appointed Medical Officer of Health to the City of Coventry and Medical Superintendent to the City Fever Hospital.

STEVENS, A. E., M.B. Durb., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

STURGES-JONES, W. E., M.R.C.S. Edin., L.R.C.P. Lond., L.S.A. Lond., has been appointed Vice-Consul for the Perené and Chanchamayo Districts of Central Peru, South America.

TAYLOR, HENRY J., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Manchester Royal Eye Hospital, vice W. E. Smith.

THWAITES, G. B., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

TUDBY, A. H., M.S., has been appointed Surgeon to In patients on the Honorary Medical Staff of the Evelina Hospital.

WINSTAN, ST. ANDREW ST. JOHN, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Derbyshire Royal Infirmary, vice Reginald H. Hill.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index)

BELGRAVE HOSPITAL FOR CHILDREN, Gloucester-street, S.W.—House Surgeon for six months. Board and residence in the hospital and an allowance of £5.

BETHLEM HOSPITAL.—Two Resident House Physicians for six months. Apartments, complete board, and washing provided.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer. Salary £100 per annum, increasing £10 yearly to £120 per annum, with board, lodging, washing, and attendance.

DOVER HOSPITAL.—House Surgeon, unmarried. Salary £100 a year, with board and lodging.

EXETER CITY ASYLUM.—Assistant Medical Officer. Salary £120 per annum, rising by £10 yearly to £150, with board, lodging, and washing.

GENERAL HOSPITAL, Birmingham.—Ophthalmic Surgeon (Honorary). Also Dental Surgeon. Honorarium of £50 per annum. Also House Surgeon. The appointment is for six months. There is no salary, but residence, board, and washing will be provided. Also Pathologist. Salary £100 per annum, with board and residence. The appointment will be subject to annual re-election, to a limit of five years. A knowledge of bacteriology will be deemed essential. Also two Assistant House Physicians for six months. There is no salary, but residence, board, and washing will be provided.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Resident House Physicians.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.—Three Senior Clinical Assistants. The first appointment will be for six months, but is renewable at the discretion of the Committee of Management. Also Resident Medical Officer. Salary £50 per annum, with board, residence, and washing.

LEEDS CITY HOSPITALS.—Assistant Resident Medical Officer. Salary £150 per annum, with board, lodging, &c.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon. Honorarium at the rate of £50 per annum and board.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon for six months. The House Physician and House Surgeon each receive a salary at the rate of £40 a year; the Assistant House Physician and Assistant House Surgeon each receive a salary at the rate of £20 a year.

MONSALL FEVER HOSPITAL, Manchester.—Medical Assistant at £100 per annum, with board and lodgings.

NEW HOSPITAL FOR WOMEN, Euston-road.—Three Clinical Assistants (women) in the out-patient department, to attend on Tuesday, Wednesday, or Friday. The appointments are for one year.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Assistant to House Surgeon for six months. Board, lodging, and washing provided. No salary.

PARISH OF WESTRAY, Orkney.—Medical Officer and Public Vaccinator. Salary £90 per annum.

PRESTON ROYAL INFIRMARY.—Assistant House Surgeon. Salary £50 per annum, with board, rooms, washing, &c.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £30 per annum, board and washing provided.

ST. GEORGE-IN-THE-EAST.—Infirmary and Workhouse Assistant Medical Officer. Salary £120 per annum, with rations and apartments.

ST. MARY'S CHILDREN'S HOSPITAL, Plaistow, E.—Ophthalmic Surgeon. Also Assistant Resident Medical Officer for six months. Salary at the rate of £40 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £70 per annum, with board, washing, and residence. Also a Junior Assistant House Surgeon. Salary £2 per mensem, with board, washing, and residence.

TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon (to act also as Secretary). Salary £60, with board, lodging, and washing.

UNIVERSITY OF ST. ANDREWS.—Professor of Midwifery.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and House Surgeon for six months.

Births, Marriages, and Deaths.

BIRTHS.

BLOMFIELD.—On August 26th, at The Horsefair, Pontefract, the wife of Geo. Wills Blomfield, M.R.C.S., L.R.C.P., and L.S.A. Lond., of a daughter.

BLUMER.—On August 30th, at St. Mary's-grove, Stafford, the wife of F. Milnes Blumer, M.D., of a son.

FRANCIS.—On August 29th, at Uxbridge, the wife of L. A. Francis, M.R.C.S., L.R.C.P., of a son.

GOSSE.—On August 25th, at Eccleshall, Staffs., the wife of Hope Wilkes Gosse, M.R.C.S. Eng., L.R.C.P. Edin., of a son.

HARDYMAN.—On Sept. 5th, at Bath, the wife of George Hardyman, M.B., F.R.C.S.E., of a daughter.

LAZARUS-BARLOW.—On August 31st, the wife of W. S. Lazarus-Barlow, M.D., of a son (stillborn).

REYNOLDS.—On August 28th, at 81, Hornsey-rise, London, N., the wife of Austin Edward Reynolds, M.R.C.S., of a son.

RYLE.—On August 26th, at German-place, Brighton, the wife of Reginald John Ryle, M.D., of a son.

SHAW.—On August 24th, at Sedgomoor, St. Austell, Cornwall, the wife of Archibald Shaw, M.D. Glasg., of a son.

STAVELEY.—On Sept. 3rd, at South Eaton-place, S.W., the wife of W. H. C. Staveley, F.R.C.S., of a daughter.

WOOLBERT.—On August 9th, at Landour, India, the wife of Major H. R. Woolbert, of a daughter.

MARRIAGES.

ABERNETHY—LYALL.—On Sept. 1st, in St. Thomas's Church, Haverfordwest, by the Rev. Atterbury Thomas, Robert Abernethy, M.D., F.R.C.P. Edin., to Frances Elizabeth, daughter of the late David Lyall, M.D., Deputy-Inspector-General of Hospitals and Fleets, R.N.

CRAWFORD—WILLIAMSON.—On August 31st, Cyril Rodney Holtz Crawford, M.R.C.S., of Pembury, Kent, to Lucy Phillis, second daughter of George Williamson.

DAVIS—GILL.—On Sept. 7th, at Christ Church, Marylebone, John Warren Davis, M.R.C.S. Eng., L.R.C.P. Lond., to Agnes, widow of the late Edmund Richard Gill, of Kimberley, South Africa.

DURRAN—SMITH.—On August 30th, at Bank of Scotland House, Kirriemuir, by Rev. James Durran, M.A., Queen-street F. C., Edinburgh, brother of the bridegroom, assisted by Rev. William Kirkpatrick, South F. C., Kirriemuir, and Rev. Gilbert Laurie, M.A., Fairbairn Memorial F. C., Glasgow, John George Durran, M.B., C.M., Kirriemuir, to Flora Margaret, elder daughter of Archibald Smith, Solicitor, Kirriemuir.

DYER—PRICE.—On Sept. 3rd, at St. Luke's, Uxbridge-road, W., Sidney Reginald Dyer, M.D., M.R.C.S., Barrister-at-law, of the Middle Temple, and Deputy Medical Officer of H.M. Prison, Wandsworth, to Rose, daughter of Henry Talbot Price.

JONES—GRUGGEN.—On Sept. 1st, at Amport, Andover, by the Rev. G. S. Gruggen, vicar of the parish, assisted by the Rev. Alfred Jones, late vicar of St. John's, Kenilworth, and by the Rev. E. G. Watts, brother-in-law of the bride, Edward Jones, M.R.C.S., of St. Columb, Cornwall, elder son of the Rev. Alfred Jones, to Josephine, third daughter of the Rev. G. S. Gruggen.

MONSARRAT—TURNEY.—On Sept. 6th, at Nottingham, Keith Waldegrave Monsarrat, F.R.C.S.E., of Liverpool, to Marguerite Ada, second daughter of Alderman Sir John Turney, J.P., of Nottingham.

NUTTALL—STEAD.—On August 25th, at the Parish Church, Leamington, by the Rev. Cecil Hook, vicar, assisted by the Rev. Murray Ragg, brother-in-law of the bride, Arthur Peel Nuttall, M.D. Lond., of Bury, Lancashire, to Dorothy May, fifth daughter of the late Maud Stead, of Harrogate, and of Mrs. Stead, of Leamington.

POOLE—HARLAND.—On August 22nd, at Holy Trinity Church, Ryde, I.W., by the vicar, Rev. W. M. Cameron, M.A., W. Evered Poole, Major, late 60th Royal Rifles, to Fanny Kate Elliott, younger daughter of Henry Harland, M.D., of Eastridge, Ryde, I.W., fomerly of Wadhurst and Tunbridge Wells.

SPICER—HUNTER.—On July 7th, at Marylebone Parish Church, by the Rev. F. Eliott, M.A., vicar of St. Luke's, Oseney-crescent, assisted by the Rev. Alfred Pugh, Assistant Chaplain to H.M. Prison, Holloway, Frederick Spicer, M.D., of Devonshire-street, Portland-place, elder son of Frederick Spicer, M.R.C.S., of Carleton-road, Tufnell-park, to Florence Annie, third daughter of the late Richard Hunter, of The Elms, Hilldrop-road, N.

WAINWRIGHT—CAVELL.—On August 25th, at St. Helen's Church, Ore, Sussex, William Longworth Wainwright, M.B., B.Sc., of Brixworth, Northamptonshire, to Mary Lilian, youngest daughter of the Rev. Frederick Cavell.

WALKER—PEDDER.—On Sept. 6th, at St. Michael and All Angels, Helensburgh, by the Rev. W. Perowne Holmes, Vicar of St. Peter's, Leicester, assisted by the Rev. J. Stuart Syme, Rector of St. Michael and All Angels, Walter W. Walker, M.B., B.C. Cantab., Peterborough, to Margaret, youngest daughter of William Pedder, Stirling.

WILSON—HANBURY.—On Sept. 2nd, at Chefoo, China, William Wilson, M.B., C.M., to Elizabeth, second daughter of Cornelius Hanbury, of Richmond, Surrey.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898, bound in cloth, gilt lettered, price 18*s.*, carriage extra; and Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*, can be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8

Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

THE COMMENDATORE DR. LAPPONI, BODY-PHYSICIAN TO THE POPE.

OUR Rome correspondent writes:—Giuseppe Lapponi studied medicine at the Bologna school, where he distinguished himself in the classes of Professor Concato and Professor Murri, the latter a pathologist and surgeon of high repute, and well known to the professional world as a contributor to THE LANCET. He graduated as Doctor in Medicine in 1875, and after for a brief interval assisting the Professor of Pathological Anatomy in Bologna, Dr. Tartuffi, he went into general practice, first at Capalone, in Tuscany, and next at Pollenza, near Macerata. There he remained till 1885, recommending himself by his skill.

Digitized by Google

his fertility in resource, and his self-reliance, while contributing with much acceptance to medical periodicals, Italian and French. In 1888 he had transferred his *penates* and practice to Osimo, when one day he received from the Vatican an invitation to become the Pope's body-physician, the holder of that post, who had also held it in the latter years of Pio Nono, being Dr. Alessandro Ceccarelli, an excellent practitioner who had won his fame as a surgeon and was by this time well stricken in years. Dr. Lapponi's reply was in the affirmative and he accordingly repaired to Rome, at first as assistant to Ceccarelli, who required him to pay a weekly visit to the Vatican, while still keeping a *pied-à-terre* at Osimo. This arrangement did not last long. Ceccarelli died and Dr. Lapponi succeeded him as "archiatro di Sua Santità" (physician-in-chief to His Holiness). In this position he speedily won the entire confidence of his august patient, who placed the whole management of his health unreservedly in his hands and came to consult him—as Pio Nono used to consult Ceccarelli—even on matters but remotely connected with the healing art. As years rolled by and His Holiness began more and more to feel their weight, Dr. Lapponi's attendance at the Vatican became gradually more assiduous, till of late his ordinary visits are never fewer than thrice weekly, sometimes every day, at others (when occasion requires) as often as three or four times in the 24 hours. As to the Pope's recent illness, or rather mild indisposition, of which the Continental press made so much, Dr. Lapponi gave no countenance to the alarmist reports set in circulation. His Holiness, according to Dr. Lapponi, was unwell for no more than two days—the cause, a slight access of intestinal catarrh due to the excessive heat. Hardly any treatment was resorted to—repose, absolute repose, was the line indicated; while, to put an end to the reports aforesaid Dr. Lapponi caused an editorial announcement to be made in the official organ of the Vatican—the *Osservatore Romano*—describing the clinical *status quo*. His Holiness himself used to smile gently at the sensational "intelligence" as to his condition, and always fell back on the directions of his physician, in whose hands his wiry, unbroken constitution had, he felt, all justice done to it. In March next he will be a nonogenarian, but Dr. Lapponi ventures to predict that—if no unforeseen complication occur—His Holiness will betray but small indication of the senile state. One reassuring feature in his case is the marvellous alertness of mind, above all the ready and unimpaired memory which never fails to recall names, events, and places with a precision, a promptness, and an accuracy which are the envy of his court. His faculties he maintains in admirable exercise, and on the Sunday succeeding his last illness (on August 21st) he recited to his physician twelve stately hexameter lines which he had composed in bed the night before, because he felt more wakeful than usual. Hygienic conditions, much more than active treatment, are what Dr. Lapponi relies on for the health of his patient, and among these are the avoidance of extremes of cold in winter and of heat in summer, the latter secured by four ventilators of the doctor's own devising by which the Holy Father's study and dormitory and audience-chambers are kept deliciously cool without draughts or sudden alternations of temperature. As to the Pope's daily life, it is already known to readers of THE LANCET. Early rising is secured by his being always in bed by 9 P.M., and the frugal meals he takes—*una piccolissima colazione* (a very slight breakfast) shortly after he gets up at 7 A.M. and a quite frugal dinner at 2 P.M.—amply suffice for the audiences, the correspondence, the composition of the allocutions, the encyclicals and the bulls which form so important a feature of the pontifical year. It is quite a mistake to suppose that he has in any way relaxed his solicitude as to official cares, ecclesiastical or other. He is closeted daily, and often for hours, with his Cardinal secretary, Monsignor Rampolla, whom he never keeps waiting, and, the moment the conference is over, he resumes his work, theological or ecclesiastical, as aforesaid, without perceptible loss of energy. Add to all this his delight in conversation when a congenial interlocutor presents himself, occasions on which he pours forth historical, literary, artistic and even scientific lore, amassed during long years of devotion to books—and some notion may be formed of the personality for whose bodily health and mental vigour Dr. Lapponi is not only answerable but effectively responsive.

WANTED A SCHOOL FOR THE DEAF AND DUMB.

A CORRESPONDENT asks for the address of a good boarding-school for a boy about ten years old who is deaf and dumb.

PULEX IRRITANS.

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of May 14th, 1898, an editorial note in reply to a correspondent who had written to you to inquire "the best way of exterminating the flea-pest." For personal use the chloroform method suggested in your note is certainly the best. In particularly hot summers the resident staff of the London Hospital, when engaged in receiving-room and out-patient duty, were, in my time, always armed with a chloroform drop-bottle and at the least sign of irritation a few drops were poured on the clothing over the affected spot. But this method is not available for the general public and it is, moreover, defence at too late a stage. The best method of prevention lies in the annihilation of the breeding-places of the fleas. The larvæ are nourished on minute blood-clots deposited by the female flea in dirty clothing, carpets, cracks in the floor, and other convenient places.

According to one of the minor characters in Shakespeare fleas breed in putrid urine:

Second Carrier. I think this be the most villanous house in all London road for fleas. I am stung like a tench.

First Carrier. Like a tench! by the mass, there is ne'er a living christen could be better bit than I have been since the first cock.

Second Carrier. Why, they will allow us ne'er a jordan, and then we leak in the chimney; and your chamber-lye breeds fleas like a loach. *King Henry IV.*, Part I., Act 2, Scene 1.

But this interesting observation in natural history lacks confirmation.

With proper cleanliness the eggs or larvæ should be destroyed at some time during the fourteen days occupied in the developmental process. In many badly constructed houses, however, with gaping cracks in the flooring, under the skirting board, &c., true cleanliness is hardly attainable. In such cases one of the various vegetable products which destroy or annoy the fleas may be freely used. In your note you mention common English lavender, but this is of doubtful efficiency. The powder of the dried flowers of various species of pyrethrum (the so-called "Persian" insect powder) stupefies and finally kills fleas and most other insects. In common use for many hundred years have been wormwood (Artemisia) and fleabane (Pulicaria). Of the former Tusser writes—

> "Where chamber is swept and wormwood is strown,
> No flea for his life dare abide to be known."

But the cheapest and most efficient of all the powders employed for this purpose is powdered fennel. My attention was first directed to its use by a note in Dr. Lauder Brunton's Materia Medica, second edition, page 852. "I am informed," he writes, "that the wild fennel growing in South Africa will completely drive away fleas from kennels and stables, and powdered fennel has a similar effect in this country." The powder must be used very freely and will then be found singularly effective. In a tenement house inhabited by some friends of mine in the Jews' quarter of East London, in which owing to the numerous floor-cracks which no broom could penetrate thorough cleanliness had failed to eradicate the pest, the floors and furniture were, on my advice, freely sprinkled with powdered fennel. In a fortnight the fleas had all disappeared, never to return.

I am, Sirs, yours faithfully,

Nagasaki. M. E. PAUL.

VISUAL PERCEPTION OF THE THIRD DIMENSION.

IN the July number of the *Psychological Review* Professor Charles H. Judd of New York University discusses various explanations of the visual perception of depth. After describing experiments with a thread extended forwards from the bridge of the nose and criticising the theory which makes sensations of movement the especial factor of all space-perception, he concludes as follows:—

> "Visual depth is thus conditioned by a certain relation of contradiction between the two-dimensional data of the retinal image or between the muscle-sensations which are connected with these images. The agreement between the elements in which the contradiction appears must be great, but it must not be complete, for the contradiction is an essential element. Depth, then, may be properly defined as a form rather than as a content of perception. It is not in any sense an original attribute of sensation. ..... It is, of course, like all psychical experience, subjective, but its source is just as much objective as is that of the sensation qualities which are arranged in space."

THE POST OF MEDICAL OFFICER OF HEALTH AT BINGLEY.

THE *Bradford Observer* recently contained an advertisement from the Bingley Urban District Council which ran as follows:—

> BINGLEY URBAN DISTRICT COUNCIL.
>
> The Council propose to appoint a MEDICAL OFFICER OF HEALTH for the district of Bingley, comprising an area of 11,800 acres and a population of 18,500. The appointment will be made subject to the regulations of the Local Government Board, under their General Order of the 23rd March, 1891.
>
> Applications, stating salary required, to be addressed to me not later than Saturday, Sept. 10th.
>
> R. ARMISTEAD, Clerk to the Council.
>
> Town Hall, Bingley, August 20th, 1898.

That candidates should themselves state the salary for which they would be willing to work is, in our opinion, a most unfortunate feature in the projected appointment. The words of the advertisement suggest that the Bingley Urban District Council are prepared to hand over the care of the public health of the community to the medical man making the lowest tender.

DANGERS OF CHRYSAROBIN.

IN the *Deutsche Medicinische Wochenschrift* of August 25th Dr. Max Linde, an ophthalmic surgeon in Lübeck, describes the case of a man who suffered severely as a result of treatment with chrysarobin ointment. He had for seven years been the subject of general psoriasis, but was otherwise healthy and was free from syphilis. Four years ago the disease almost entirely disappeared after painting with a solution, but this was followed by a relapse and for the last two years the eruption has covered the whole body with the exception

Digitized by Google

of some limited spaces. Since the beginning of last January the medical man in attendance had made use of iodide of postassium, sulphur ointment, pyrogallol dissolved in traumaticin, and Fowler's solution, but as no improvement was produced he adopted active treatment with chrysarobin. From Feb. 23rd to Feb. 28th he used a weak ointment of Goa powder and vaseline (1 to 8), and from Feb. 28th to March 21st a stronger ointment consisting of 1 part Goa powder to 4 parts vaseline. The patient was warned of the danger to his eyes, and he carefully followed the directions given him for their preservation; but eighteen days after the commencement of the treatment their condition was very bad. In the right eye the conjunctiva was extremely red, velvety, and somewhat swollen; the cornea was white (*milchig*) and opaque, and at the meeting of the lids the epithelium was absent over a space of ¼ in. (8 mm.) long and ¼ in. (5 mm.) broad; the sensibility of the cornea was greatly impaired but not entirely lost. The patient felt no actual pain, but only "something burning." In the left eye the corneal epithelium was macerated and wavy but not broken; its sensibility was impaired. Both pupils were of the size of pinheads and did not react. The iris was hyperæmic and the ciliary border was injected bluish-red. With the right eye a finger could be seen at a distance of 4 ft. and with the left eye at a distance of 8 ft. The urine contained abundance of albumin, red and white blood-corpuscles, and a few granular casts. The patient complained of weakness and palpitation of the heart. On using atropine and stopping the inunction he improved to some extent, but did not regain his original condition. When the last examination was made on May 22nd, eight weeks after the commencement of the treatment, his cornea showed opaque spots penetrating to the deep layers; the epithelium was smooth and gave a reflection everywhere; the pupils were of ordinary size, and reacted normally; there was no irritation. The urine still contained albumin, white blood corpuscles, and granular casts. The psoriasis had again appeared on different parts of the body, especially on the face and back; a cautious attempt to resume the treatment was in a few days followed by renewed irritation of the eyes. Dr. Linde recommends that whenever chrysarobin is used a careful watch should be kept for constitutional symptoms, such as contracted pupils, impaired sensibility of the cornea, pericorneal injection, and abnormalities of the urine, on the occurrence of which the treatment should be immediately stopped. The same precautions should be taken with pyrogallol, which is more poisonous than chrysarobin and more liable to attack the kidneys.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—I have read with interest the letter of "X." in THE LANCET of August 27th. In the town where I am in practice three of my fellow-practitioners, who are M.R.C.S., L.R.C.P., boldly write "Dr." on their doorplate and visiting cards.—I am, Sirs, yours faithfully,

August 26th, 1898. G. D. E.

REAGENTS FOR FREE HYDROCHLORIC ACID IN THE GASTRIC JUICE.

A SERIES of experiments on the identification of free hydrochloric acid in presence of acetic, lactic, and butyric acids has been made by Dr. R. Ricci at the Istituto di Clinica Medica in Milan and the results are published in the *Gazzetta degli Ospedale* of Aug. 14th. Weigert's hæmatoxylin in aqueous solution gives a very fine yellow colour with all acids; this reaction is of such delicacy that it will show traces of free hydrochloric acid inappreciable by other means. Toiseau's reagent (the composition of which, however, is not stated) is also extremely sensitive. If 1 c.c. be mixed with a like quantity of filtered gastric juice in a test-tube the organic acids cause no change, but in presence of free hydrochloric acid the violet colour becomes light blue. Tungstate of soda in saturated solution has the property of giving a white precipitate with free hydrochloric acid, but is unaffected by the other acids; 1 c.c. of it is mixed in a test-tube with from 1 c.c. to 5 c.c. of filtered gastric juice; the precipitate forms in the upper part of the tube. The other reagents experimented with were safranine, vesuvine, methyl green, dahlia, and malachite green.

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—A most annoying mention of my name having been made in an article on Buxton and its Treatment in Wednesday's *Sun*, I at once addressed a letter of remonstrance to the editor of that paper, and this duly appeared. I find, however, that an unfair use is being made of the incident, and I venture to ask you to publish this disclaimer to the medical profession. I am, Sirs, yours faithfully,

Buxton, Sept. 5th, 1898. WM. ARMSTRONG.

FORMALIN IN INSECT STINGS.

To the Editors of THE LANCET.

SIRS,—As the subject of insect stings is mentioned in a recent annotation in THE LANCET, may I point out that "formalin" (recommended some time ago for mosquito bites in one of the medical journals by a Zanzibar correspondent) is an excellent remedy for the irritation produced by the stings of all insects? The "bite" is touched with the moistened stopper of the "formalin" bottle and as soon as the application begins to smart the excess of "formalin" is wiped off; relief is almost instantaneous. I am, Sirs, yours faithfully,

F. HYDE MABKRLY.

Brooklyn, Earl's Court-square, S.W., August 30th, 1898.

Tse-Tse.—Although much work has been done on the Tse-Tse fly disease its records exist only in pamphlet form. In the recently issued work on "The Infective Diseases of Animals," a translation of vol. i. of Friedberger's and Fröhner's "Veterinary Pathology," there is an original chapter on the subject by the translator, Captain Hayes, F.R.C.V.S. The account given is, however, very short and does not add to what is already known. We know of no better pamphlet than that by Major Bruce, of the Royal Army Medical Corps, entitled "A Further Report on the Tse-Tse Fly Disease."

X. Y. Z.—1. A house surgeon is bound to obey the authorities of his hospital. He must therefore grant the certificates as he is directed by the committee. 2. He may charge no fees without leave of the governing body of his hospital. 3. The committee has a right to levy any fee it likes.

Fundus Oculi.—Our correspondent will find "Sight Testing for the General Practitioner," price 2*s.* 7*d.* post free (F. Davidson, 107, Great Portland-street, London, W.), useful for the purposes which he mentions.

Southern Cross.—Certifying surgeons under the Factory and Workshop Act are appointed by the inspectors of factories. Our correspondent should apply to Dr. Whitelegge, Home Office.

A. R. M. E., from his account of the matter, has been shabbily treated. A solicitor on seeing the letters which have passed could best say what remedy he has.

U.C.H.—The Warrant for giving substantive rank is published in our present issue but the title of Indian Medical Service is still retained.

M. D. will find our reasons in the leading article to which we have already made reference.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

WEDNESDAY (14th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (15th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex, (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

FRIDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (17th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

A Lecture
ON
TUBERCULOSIS AND THE MILK-SUPPLY, WITH SOME GENERAL REMARKS ON THE DANGERS OF BAD MILK.

Delivered at Sudbury Hall at the invitation of Lord Vernon, on Thursday, September 15th,

BY SHERIDAN DELÉPINE, M.B. EDIN., B.Sc.,
PROCTOR PROFESSOR OF PATHOLOGY, OWENS COLLEGE.

GENTLEMEN,—Some months ago Lord Vernon wrote to me with regard to the work which is being done in his Sudbury estate and with special reference to his anxiety to free all the cattle on his farms from tuberculosis. It is well known that a considerable initial expense is attendant on carrying out such a plan. The difficulty is further increased on account of the well-known tendency which practical men generally, and especially farmers, have to look with suspicion upon any new idea which is not in accordance with the practice of their predecessors. History acquaints us with the value of such arguments; if man had not from time to time risen above traditional practices we would have been deprived of the benefits of steam and electricity, or of sanitation, without speaking of greater boons still, such as the freedom of conscience and the impartial administration of justice which we enjoy under the British Constitution.

The difficulty of dealing with tuberculosis is further increased by the general ignorance of the public. The danger which they incur from a contaminated milk-supply is appalling in its magnitude, yet because this danger is of an insidious nature and its effects are often so gradual that it is difficult to trace their onset they prefer to have their quietude not disturbed. They are also afraid that their purses might have to be opened. Rather than face such possibilities they prefer to believe the few experts who still hold views which numerous most searching investigations have proved to be wrong. They still hold that tuberculosis is a disease chiefly due to climatic conditions and to hereditary tendencies. The belief that tuberculosis is transmitted from parent to offspring is one of the traditions most inimical to progress with regard to the prevention of this disease. It gives to the mind a sense either of helplessness or of the necessity of measures, such as segregation, which would be repellent to our affections and which nothing but an immense peril could induce us to contemplate.

Tuberculosis is a disease which is acquired almost invariably after birth owing to the penetration in our organs of a minute parasite. We know now this parasite and most of the ways in which it can gain entrance into our body. This being so we should be able to defend ourselves by avoiding or destroying this enemy. I am convinced that if people could see the tenth part of what we students of disease have a too frequent opportunity of witnessing they would be convinced at once of the necessity of taking proper precautions against the disease. It is this conviction which has led me to accept the invitation which Lord Vernon has done me the honour to send me and to give you a short account of tuberculosis and of the way in which milk may assist its spread. It gives me much pleasure to do what I can to assist Lord Vernon in his good work—work which is undoubtedly of great public importance. Many others might do it better than I can, but I will speak with the conviction which fifteen years of continuous pathological studies have given me. Many here are experts before whom I would hardly think it necessary to repeat what to most of them are truths firmly established; they must, however, excuse me if, keeping in mind the nature of the invitation given me by Lord Vernon, I address myself to those who have directed their activities to other fields than the study of disease. Perhaps had I known that instead of coming here to give some information to Lord Vernon's tenants I should have had to address such a gathering of distinguished experts, with Sir William Broadbent in the chair, I should have accepted his lordship's invitation less readily.

Tuberculosis is produced by the penetration into various parts of our body of a very small vegetable parasite, which was first described by Koch sixteen years ago. This bacillus is quite invisible to us unless we help our powers of vision by means of the microscope. It is so small that particles of dust minute enough to be easily raised by slight currents of air may contain many of them, so that we may breathe air loaded with the parasite without our being conscious of it. In the same way it may be present in milk without our being aware of its presence. It does not multiply readily outside the body of its victims, but it has extraordinary powers of resistance. It is but slightly affected by the greatest extremes of heat or cold of our seasons; it may be kept dry for several months without dying or ceasing to be able to produce disease; it resists immersion in water, putrefaction, burying in the ground for days, weeks, or months; and the only natural agency which seems rapidly fatal to it is sunlight. It is generally admitted that this bacillus does not grow readily outside the body of animals liable to tuberculosis, yet by taking proper precautions it is not very difficult to make it grow on suitable substances, and I satisfied myself several years ago that it is quite possible for the conditions necessary to occur in nature. Up to the present time, however, we have no clear evidence that this multiplication of the bacillus outside living tissues plays an important part in the spread of the disease. I have for the last six years tried to find whether this multiplication outside the body might be of importance under ordinary circumstances but have not succeeded in coming to a definite conclusion. I will therefore assume that for the present we need only discuss the share which tuberculous men or animals have in the spread of the disease.

Let us suppose that a few particles loaded with tubercle bacilli have been carried into the lungs of a person. These bacilli will, by means of the products which they secrete, produce irritation of the part and, if sufficiently numerous or active, they will rapidly cause the deaths of a few cells. Then a fight, first described by Metschnikoff, will follow during which some of the cells composing the tissues of the person attacked will surround the bacilli, take them up into their bodies, and digest them if they can. If the cells are sufficiently active and the bacilli not too virulent the microbes will either be killed or rendered harmless and, fortunately for us, this takes place in a large number of instances. When the fight is short nothing appreciable remains to show what has taken place. If the contest is more equally balanced a number of cells die, undergo caseous degeneration—i.e., a kind of fermentation similar to that which takes place in ripening cheese—and a so-called cheesy nodule or tubercle is produced; this becomes surrounded by scar tissue and may gradually be infiltrated with lime salts. These cheesy or chalky nodules may remain in the tissues till the individual dies from some other cause. When they are found in the organs after death it is generally assumed that they indicate a victorious fight of the tissues against the microbes and for that reason these lesions are described as of "healed tuberculosis of phthisis." In many cases, unfortunately, the fight does not end so favourably. After being checked for a longer or shorter period the bacilli manage to multiply in the midst of the enfeebled or dead tissues. This takes place more specially when these tissues have been weakened by some congenital vice of constitution or by some recent disease or unfavourable condition which has reduced the activity of the cells or killed many of them. As the bacilli multiply they extend beyond the margin of the area which they first invaded. Some are carried away by wandering cells which move in a system of channels and spaces permeating all our tissues and which are known as lymphatic spaces and vessels.

On the course of the larger lymphatic vessels there are organs known as lymphatic glands or ganglia through which the lymph is elaborated and, so to speak, filtered before it can pursue its course along the lymph-vessels. Before this lymph can reach the blood-vessels it has to pass through a number of these glands. Now, the bacilli contained in the wandering cells continue their fight and the diseased cells become arrested in the first lymphatic gland which they reach which is usually very near the point where the bacilli have entered the body. I have assumed that all the bacilli are carried along by cells. This may not be the only way in which they spread along the lymphatics. The fact, however, remains that they rapidly reach the lymphatic ganglia which are connected with the place where the bacilli have penetrated. They have now reached the second line

Digitized by Google

of defence the fight is there renewed and in some cases the bacilli are checked and though they may produce extensive disease of the gland they are unable to go further. This form of tuberculosis of the lymphatic glands is generally known under the name of scrofula (one of the forms of the old king's evil), on which so much has been written. This form of disease has been lately thoroughly investigated in my laboratory by Dr. F. C. Moore, who has recently embodied the results of his experiments and observations in a most valuable monograph.[1] Out of 26 cases of chronic enlargement of the glands, mostly of the neck, which had to be operated upon for various reasons, not less than 19—i.e., a little over 73 per cent.—were found to be tuberculous.

Lymphatic glands are not the only organs which are liable to this chronic form of tuberculosis—bones and joints, for instance, are often affected in the same way. In a large number of cases, however, the bacilli pass beyond this second line of defence and, after overcoming a number of other glands, they may finally affect most of the lymphatic glands of the body. It is easy for me to demonstrate this process to you by a series of guinea-pigs inoculated with minute doses of tuberculous matter taken either from human or bovine lesions. Tuberculosis has a remarkable tendency to remain confined to the lymphatics and to certain internal organs for a comparatively long period. The spread of the disease along the lymphatics presents a remarkable peculiarity to which I attracted the attention of pathologists some years ago.[2] After following the course of the lymph so closely for a time, that only those glands receiving lymph from the part infected become diseased, other glands not situated on the course of the lymph-stream become invaded as if the tuberculous process extended back against the lymph-current. Thus it is found that after the glands at the root of such organs as the lungs have become tuberculous those organs themselves usually become rapidly diseased. According to our expectations, based on current knowledge of the course followed by the lymph, the viscera should be affected first and the glands receiving the lymph from them should be affected last. I do not wish to trouble you here with a discussion of the nature of this phenomenon but its practical importance in connexion with tuberculosis of the udder is evident. Whenever the glands receiving the lymph from the udder become affected the possibility of the udder being already diseased or about to be diseased should be considered even in those cases in which the udder appears on external examination absolutely normal.

The further stages of the disease are produced in two ways. Either the interference with important organs and the generation of poisonous substances by the bacillus or both combined cause a general state of debility and fever which ends in death or the disease becomes generalised by the bacilli penetrating in comparatively large numbers into the blood-vessels. One of the ways in which this takes place is by ulceration of the walls of some veins passing through or at the side of some tuberculous focus; tuberculous matter loaded with bacilli is thrown through the opening in the walls of the vessel into the blood-stream and is distributed to all the organs of the body. Wherever the bacilli get lodged they give rise to small centres of disease similar to those which I have already described. These lesions have the form of small nodules, grey and transparent at first, becoming afterwards yellow in the centre owing to cheesy degeneration. Owing to their size being usually that of a millet-seed these tubercles are known as miliary tubercles. These tubercles may be found in all parts of the body and of course render all the tissues infectious; hence the danger of eating the uncooked flesh of animals in which tuberculosis has become general. It is for this reason that carcasses of animals affected with general tuberculosis are invariably condemned by sanitary authorities. This form of the disease is rapidly fatal.

I have passed over certain changes taking place in the lesions of localised tuberculosis in order to give you a connected view of the progress of the disease when once it has taken hold of our body or of that of an animal such as the cow, the horse, the pig, &c. There are differences in the various animals, but these need not be discussed here as they are not essential. The destruction of tissues in certain organs of the body is associated with consequences of great practical import, for it is to them that is due the danger of infection of healthy individuals by diseased ones. To make the consequences of ulceration clearer to you I will show you the effects of tuberculosis affecting the skin of the face of some patients suffering from that dreadful disease, tuberculous lupus. You notice first the effects of the reaction of the tissues giving rise to considerable swelling and deformity, then the tissues decay, soften, and crumble away, and prominent parts of the face are removed as if bitten away and may even be replaced by ghastly cavities. What takes place on the face occurs also in the lungs, the kidneys, the bowel, and the mamma when these parts are affected with local tuberculosis. Now, the mass of decayed matter which is set loose by this ulceration contains in some cases large numbers of tubercle bacilli. The ulcers which in the lungs take the form of cavities empty themselves into the air-passages from which their contents escape through the mouth when the patient expectorates or they are swallowed as soon as they reach the back of the mouth and go down the bowels where they may start fresh mischief and render excreta infectious. It is easy to demonstrate the presence of these tubercle bacilli in the expectoration of phthisical patients or animals; they can also be demonstrated in their excreta. These dried discharges scattered by draughts in the air render the houses or places inhabited by phthisical persons or animals dangerous when absolute cleanliness is not observed. This is the chief source of tuberculous disease in man, in cattle, and in some of our pets—such as dogs. Out of 80,943 persons dying from all cases in London during 1897 in no less than 10,984 cases the death was registered as due to tuberculous disease. Out of these 10,984 cases 7864 are put down to phthisis. Though it is not proved that all cases dying from pulmonary phthisis have been infected through the air passages it is reasonable to assume that most of them have.

In the same way as bacilli are liberated from the lungs and scattered outside the body they are by the same process of ulceration set free in the intestine, in the kidney, in the mamma, and in subcutaneous lesions and pass out of the body with excrements, urine, milk, and purulent discharges. Now some of these products after becoming dry may infect fresh victims by contamination of the air just as dry tuberculous sputa have been shown to do. But with milk the case is different. It is through the intestine that tuberculous milk attacks the body. It has been denied that the consumption of tuberculous milk is attended with serious danger. I think, however, that there is a sufficient number of instances in which this danger has been proved by the actual occurrence of tuberculosis in children who have been fed on milk from tuberculous cows. By experiments on young animals such as kittens, rabbits, pigs, and calves, it is quite easy to produce tuberculosis by feeding these animals on tuberculous milk or other tuberculous products. Thirty years ago, that is about three years after Villemin had announced and admirably proved that tuberculosis was an infectious disease communicable from man to animal and from animal to animal (and not essentially a constitutional one as was then believed), Chauveau demonstrated experimentally that tuberculosis could be induced in cattle by feeding them on tuberculous products. Nearly thirty years have been necessary to allow public opinion to come to the conclusion that these men of science were right. In the reports of the last two Royal Commissions on Tuberculosis we find the following statement: "No doubt the largest part of the tuberculosis which man obtains through his food is by means of milk containing tuberculous matter." It is difficult to prove when a child dying from tuberculosis has been infected through milk because before the death occurs or the disease becomes manifest the milk supply may have often been changed and milk diet has often given place to ordinary diet. As I have said there are cases in which no such doubt exists and in which tuberculosis has been traced to the consumption of tuberculous milk. Lord Vernon and Dr. Livesay have informed me that they know of a farm where such a case has occurred. There are, however, very often clear indications in the body of the victim showing the channels through which the bacilli have penetrated. We have seen how the bacilli infect first the lymphatic glands nearest to their point of entrance. The lymph coming from the intestine passes first through the mesenteric glands. The lymph from the lungs passes in the same way through the bronchial glands. It is therefore evident that in the event of the bacilli penetrating through the intestine the mesenteric glands would be chiefly affected and in the case of lung

[1] Vict. M.D. Dissertation, Manchester, 1898.
[2] Brit. Med. Jour., September, 1893, and March, 1894.

Digitized by Google

infection the bronchial ganglia would be most involved. There are cases in which death occurs before any other glands than those first invaded have had time to become diseased; in such cases the state of the glands will clearly indicate the channel through which the bacilli have entered.

In a series of over 300 experiments I have found that tuberculosis of the mesenteric glands occurs extremely late in guinea-pigs infected through other channels than the intestinal canal and the peritoneal cavity and am absolutely convinced of the value of lymphatic glands as indicators of the path followed by tubercle bacilli in cases which have died before the disease has become too advanced. According to Dr. Woodhead the post-mortem examinations of the bodies of tuberculous children who had died before the age of five and a half years show that in the large majority of them the intestine and mesenteric glands were affected and that in 14 per cent. of those cases the mesenteric glands alone were tuberculous.

A very striking proof of the frequency of infection through the intestine fell under my notice six years ago. Dr. Simcock[3] was investigating in my laboratory the pathology of chronic wasting of children due to improper feeding. He selected 13 cases out of many more in which there was no evidence of tuberculosis in the parents or in the various organs of the children as examined in the post-mortem room. He considered these cases free from tuberculosis. I was not, however, quite convinced. We carefully examined the mesenteric glands of all these children with the object of discovering whether some might not be tuberculous. In 2 of these cases the mesenteric glands showed clear tuberculous lesions under the microscope and in 5 more the mesenteric glands presented lesions suggesting the possibility of incipient tuberculosis.

The presence of two clear cases of tuberculosis among 13 cases carefully selected as free from tuberculosis is specially significant. It is also interesting to notice that the only clear lesions were found in children over ten months of age, as will be seen in the following table:—

Children Dying from Chronic Wasting with no Clinical or Post-mortem Naked Eye Evidence of Tuberculosis.

No. of case.	Age of children.	How long after birth suckled by mother.	Lesions in mesenteric glands.	
			Indefinite.	Tuberculous.
6	3 months.	Not at all.	0	0
1	3½ ,,	1 month.	Slight.	0
2	3½ ,,	2 weeks.	Slight.	0
7	4 ,,	2 ,,	0	0
8	4 ,,	2 ,,	Slight.	0
4	4 ,,	A few weeks.	Slight.	0
5	4 ,,	Not at all.	Slight.	0
9	5 ,,	1 month.	0	0
10	6 ,,	2 months.	Slight.	0
11	10 ,,	3 ,,	0	0
13	10 ,,	Not at all, cow's milk from first.	—	Well marked.
12	11 ,,	2 weeks.	Slight.	0
3	18 ,,	3 months.	—	Distinct.

Out of 4 children above ten months 2 were tuberculous. These numbers are too small to allow one to generalise from them but they assist us to understand the statistics referring to infant mortality. If we now compare with these results the returns given by the Registrar-General in his annual summary for 1897 we find that it is during the first five years of life that most deaths attributable to tabes mesenterica, scrofula, and forms of tuberculosis other than pulmonary phthisis occur. In the case of phthisis it is between the twentieth and the sixtieth year that the greatest number of deaths take place.

It is therefore clear that if infection through the air passages is well proved to be the most important cause of phthisis, the same mode of infection is not equally at work in the production of other forms of tuberculosis. Of the deaths from tuberculosis which occur during the first year of life very few occur during the first ten weeks. On the other hand they become very numerous as soon as children reach the age of six months, at which age a very large number of them have been fed for three, four, five, or even six months on cow's milk. We have also abundant observations to show that calves are exceedingly rarely born tuberculous. A few cases have been reported by various observers. Only three such cases have come under my own observation and I have been able to investigate only one of them thoroughly, through Mr. Holburn's kindness, and found

that one half of the uterus of the dam was in an advanced state of tuberculosis, a lesion of the uterus which is of rare occurrence. This instance shows only the possibility of the fœtus being occasionally infected by the womb, which is a very different thing from hereditary transmission. We have also the results of the inspection of a very large number of calves, heifers, oxen, cows and bulls. The statistics collected by various observers show that whilst it is difficult to find districts where as many as 2 calves in 1000 are affected with tuberculosis, it is, on the contrary, unusual to find out of the same number less than from 400 to 500 animals over one year old in a state of more or less advanced tuberculosis (see statistics quoted in Report of Royal Commission, 1898). The results of the testing of 39 head of cattle on Mrs. Ashton's estate at Ford Bank, near Manchester, are very instructive in this respect. After discussing the matter with me Mr. G. Ashton determined to have all the cattle kept at Ford Bank tested with tuberculin, all the animals reacting isolated at once, and those not reacting placed in disinfected stables. The diseased cows were to be replaced only by others which would have been proved by the tuberculin test and careful veterinary inspection to be free from tuberculosis. This was carried out by Mr. Locke and by Mr. King with the assistance of Mr. Holburn. Mr. G. Ashton has very kindly allowed me to make use of the results obtained, being himself most anxious to investigate the whole question.

Results of the Testing by Tuberculin of 39 Head of Cattle at Ford Bank, Didsbury, near Manchester, 1898.

These results give the following distribution of tuberculosis in cattle according to age :—

	Tuberculous.	Not tuberculous.
Under 1 year (5 cases tested)	0	5
One year and under 3 years (17 cases) ...	6	11
Three years and under 5 years (8 cases)...	5	3
Five years and over (9 cases)	6	3
	17	22

Having now given evidence to show that the prevalence of tuberculosis in the young is in most cases due to infection, and that in man this mode of infection is responsible for a considerable loss of young life, I wish to say a word more as to the influence of hereditary tendencies. If children or young animals are extremely rarely born tuberculous, how are we to account for the fact that the disease so very often attacks member after member in the same family? There are two factors which account for this: (1) the children of diseased parents are often weak at their birth and their tissues are less able to stand the fight against the bacilli when these gain entrance into the body than stronger children would; and (2) they are born in infected places and often nursed for a considerable time by persons affected with tuberculosis. Thus these weak individuals, who should be more than any others protected against the risk of infection, are by the fact of their birth in an infected family or house more exposed than stronger children would be. We know, however, for certain that by preventing infection after birth the children of tuberculous parents may be made to escape tuberculosis entirely. The same has been proved over and over again with regard to cattle. The statistics given previously show that infection takes place chiefly during the first year, at a time, therefore, when a large number of children are fed on cow's milk partly or entirely. It has been proved abundantly that by feeding them on tuberculous milk it is easy to produce tuberculosis in most kinds of young domesticated animals.

Can we find any evidence in the milk itself of the presence of the tubercle bacillus? And is the occurrence of the bacillus in milk sufficiently frequent to justify any serious fears in connexion with the use of this article of diet? In dealing here with this question I suppose that results obtained in this part of the country will prove specially interesting. I will, therefore, make use only of the data obtained in my laboratory and relating to milk coming chiefly from various farms situated in the counties of Derbyshire, Lancashire, and Cheshire. The observations I am going to relate were mostly made in the course of investigations instituted by Dr. Hope, the medical officer of Liverpool, and Dr. Niven, the medical officer of Manchester. Dr. Hope's object was chiefly to ascertain what proportion of the milk reaching Liverpool in various ways was tuberculous. He had samples of milk taken at railway stations and various town dairies and sent to various bacteriologists to be examined for tubercle bacilli. Some 50 samples were sent to me in this way.

In Manchester, where I had often the opportunity of discussing the matter with my colleague Dr. Niven, we came to the conclusion that a complete investigation should include (1) the examination of milk from cows certainly tuberculous, with and without tuberculous udders; and (2) that of milk from farms or various parts of the country and also of milk obtained from town byres and dairies. Dr. Niven's object, like that of Dr. Hope, was to find out how much tuberculous milk was used by town consumers in order to ascertain exactly the extent of the danger. Through his kindness, however, I was able to obtain information collected by the chief veterinary inspector, Mr. King, and his assistants, as well as notes regarding the situation and condition of the various farms or dairies from which milk was obtained. In addition to the samples sent to me from Manchester and Liverpool I have obtained myself a number of samples from healthy or diseased cows. During the last four years, and chiefly during the last two, I have thus had to examine some 208 samples of milk, of which 7 were from cows not known to be tuberculous; 22 were from cows nearly all in an advanced state of tuberculosis; 54 were from town dairies; and 125 were from country farms being collected by sanitary inspectors at the railway stations immediately on arrival of the cans from the country. Time does not permit me to describe the methods which I used in this investigation. I have described them in other places.[4] It will suffice to say that all these milks were (1) collected in sterilised vessels and rapidly examined on their arrival at the laboratory; (2) the colour, reaction, specific gravity, and proportion of cream and sediment were noted; (3) the sediment (or slime) and often the cream were separated by centrifugalisation and examined microscopically for dirt, morbid products, various cocci, bacilli, vibrios, yeasts, and moulds; (4) guinea-pigs were inoculated with small quantities of sediment, and, after their death, dissected in order to find whether any lesions had been produced; and (5) the lesions produced in the guinea-pigs were further examined in various ways for the purpose of finding out whether they had been produced by the bacillus tuberculosis or other microbe.

I need not say that an investigation of this kind implies a considerable amount of work. The first half I carried out mostly alone, but in the second half I have had considerable assistance, more especially from Dr. E. J. Sidebotham, and also from Dr. Moore, and lately from Dr. Carver. I have taken the greatest care from beginning to end to avoid as far as possible any source of fallacy. I may tabulate the results obtained as follows :—

A.—UNMIXED MILK COLLECTED IN STERILISED BOTTLES DIRECT FROM THE COW WITH CARE TO AVOID DIRT.

1.—Cows showing no evidence of Tuberculosis.

	Actual No. of samples.	Per cent.
1. *a.* Innocuous milk	6	85·68
b. Milk causing slight local irritation of the tissues near the point of inoculation ...	1	14·28
2. Milk causing severe œdema, ulceration, or suppuration at the seat of inoculation (local infection) or at some distance ...	0	0·0
3. Milk causing general infection, rapidly fatal (from 24 to 48 hours after inoculation) ...	0	0·0
4. Milk causing tuberculosis	0	0·0
	7	100

2.—Cows showing Distinct Evidence of Advanced Tuberculosis, Udder Diseased in 8 Cases and Suspicious in 8 others.

	Actual No.	Per cent.
1. Innocuous	10	45·40
2. Local infection, &c.	6	27·24
3. General infection, &c.	0	0·0
4. Tuberculosis*	6	27·24
	22	99·88

* In all these cases there was evidence of disease of the udder.

B.—MIXED MILK COLLECTED IN STERILISED BOTTLES FROM MILK CANS.

3.—Town Dairies (Liverpool 50 samples).

	Actual No.	Per cent.
1. Innocuous	33	61·05
2. Local infection	13	24·05
3. General infection	5	9·25
4. Tuberculosis	3	5·55
	54	99·90

4.—Country Dairies (Milk collected at Railway Stations in Liverpool and Manchester—Manchester, 93 samples).

	Actual No.	Per cent.
1. Innocuous	70	56·0
2. Local infection	21	16·8
3. General infection	12	9·6
4. Tuberculosis	22	17·6
	125	100

The meaning of these results is very clear. 1. The milk of non-tuberculous cows does not produce tuberculosis. 2. The milk of at least 1 out of every 4 cows much affected with tuberculosis is capable of communicating tuberculosis. 3. The milk coming from country farms which are not under the constant supervision of the health authorities is capable of communicating tuberculosis in 17·6 per cent. of the cases examined. A little more than 1 sample out of every 6 examined proved infectious. This comes from the extreme prevalence of tuberculosis in the country and of the mixing of tuberculous milk with good milk. Dr. Rivers informs me that after receiving the results of my examinations he asked Mr. King to visit the cowsheds from which milk had come which had been found tuberculous. Mr. King found that in all these byres (18) but one there were cows with diseased udders, which, as far as it was possible to ascertain by clinical examination, were probably tuberculous. 4. In towns, such as Liverpool, where cowsheds are under constant supervision, the number of cases in which the milk proved to be infectious was considerably less, being reduced to 5·55 per cent.

About 1 sample out of every 17 was found capable of producing tuberculous infection. This shows conclusively that improvement may be obtained by using proper measures, but that the sanitary authorities have not so far been able to remove entirely the evil. I wish to point out also that milk is capable of producing serious troubles other than tuberculosis. This is specially true of mixed milk, which, whether it comes from the country or from the town, is capable of producing a very serious form of infection—in fact, a septicæmia in some 9 per cent. of the cases examined. In addition to this from 16 to 24 per cent. of the samples are capable of producing considerable irritation of the tissues.

In a previous communication I have shown that these noxious properties were mostly due to the contaminations of the milk either at the time of milking or afterwards by the dirty vessels in which it is kept. The microbes thus introduced into the milk are of various kinds and when the temperature is high and the milk kept too long certain noxious bacteria multiply rapidly and render the milk dangerous. These bacteria may produce an infection on their own account, or, by irritating the bowel, prepare the way for the penetration of the tubercle or other bacilli. To test the truth of this supposition I have during the last summer kept in ice all the milk which had to be examined more than 6 or 8 hours after milking, with the result that only 1 out of about 30 specimens so treated has given rise to general septic infection. I show you plate cultures of milk proving the effect of cold on the bacteria in milk. You can see that milk kept four days in ice contains fewer bacteria than it did half an hour after milking.

You may ask whether inoculation of milk into the tissues is a proper test to apply in estimating the value of an article of food which in the natural course of things has only to pass into the alimentary canal. I have not asserted that all the samples of milk which I have found to produce disease when injected into the tissues would necessarily have produced disease in the human subject, but what I intend to convey is that unsound milk has properties which are not present in good milk and that these properties are of a dangerous nature. Milk may be obtained which is capable of standing the test and we have seen that milk when collected so as to avoid dirt, and kept under conditions not favouring the multiplication of bacteria, never produced a general infection rapidly fatal. This being the case there seems to be no necessity for allowing milk with unpleasant properties to reach our markets. The fact that about 60 per cent. of the milk supplied by our dairies is perfectly innocuous shows that it is not impossible to supply absolutely wholesome milk. Whether therefore the tests I have used are severe or not they show that milk of two distinct qualities is sold to the consumer: (1) milk which cannot produce any form of disease even under the conditions most favourable to the production of disease; and (2) milk which under the same conditions produce various forms of disease, some extremely severe. I think everybody will admit that this second quality is not desirable. After considering the danger let us consider the remedy.

On a previous occasion [5] I have expressed an opinion as to the public measures which seemed to me to be necessary for dealing adequately with tuberculosis from the public and administrative point of view and I can only repeat now what I said then.

1. The first general measure which can be recommended for the purpose of combating tuberculous infection through milk is in the hands of the consumers; it consists in boiling all the milk used. There is a strong prejudice against this boiling of milk. For my own part I think the defects of boiled milk have been exaggerated. I know families who on my recommendation have drunk nothing but boiled milk (except in their tea) for the last 12 or 13 years. I have watched children who have practically never drunk any unboiled cows' milk from the time they were weaned to the present day—i.e., in one case over 12 years and in the other case a little less—and these children have never suffered from the use of boiled milk and prefer it to unboiled milk. The great objection, however, to this easy remedy is that it does not protect us against tuberculous cream, butter, and cheese. Nor does it mitigate the dangers of infection due to the presence in our midst of so many tuberculous animals and the losses caused to the farmers by tuberculosis.

2. A second method of dealing with the milk so as to protect the consumer is to analyse samples from time to time and to reject from our markets all milk which is not free from infectious properties. This method is not a practical one; it is easy to detect common adulterations by simple chemical tests, but it is another thing to find out whether a sample of milk can produce tuberculosis or not; this may take days and meanwhile the consumer is not protected. This method can only be used for the purposes of checking other preventive measures and for that purpose it will always prove a useful adjunct.

3. We must turn to the actual source of milk—i.e., to the cow—and see that it is not allowed to contaminate our milk-supply. This means systematic inspection of our cowsheds and milch cows by competent men able to detect tuberculosis even before it has produced symptoms obvious to all. A careful veterinary surgeon can now by the application of the tuberculin test combined with a thorough inspection almost always determine whether a cow is tuberculous or not.

As it is impossible to say when the udder of a tuberculous cow will become diseased, the untreated milk of all tuberculous cows should be excluded from the market. After being sterilised by boiling or otherwise, this milk might still have a good commercial value. This method of inspection would free our markets from the greater part of the tuberculous milk which at present reaches them, yet this would do little towards stamping tuberculosis out. Tuberculous cows and tuberculous sheds would still remain a source of infection. It would therefore be necessary to (1) separate the tuberculous cows from the healthy ones; (2) to fatten all tuberculous cows for slaughter whenever the disease has not reached serious proportions and slaughter those in which the disease is advanced; (3) to disinfect thoroughly infected sheds; and (4) to improve their construction so as to allow of their being thoroughly cleaned, lighted and ventilated. These measures, although they would deal efficiently with tuberculosis as it exists at present, would certainly not prevent the action of fresh sources of infection.

4. This makes it evident that steps should be taken to prevent the introduction of tuberculous cattle into any county where it was desired to deal efficiently with tuberculosis: (1) all cattle brought into the county from neighbouring counties or from abroad should be examined first by veterinary surgeons acting under the direction of some central county sanitary authority; (2) all cattle kept in the county should also be registered and marked, so that it should be easy to ascertain which animals have been registered, inspected, and tested; (3) all cowsheds should then be inspected at least twice a year and the few tuberculous animals which would have escaped previous inspection weeded out; and (4) the breeding of healthy cattle should be encouraged and calves fed on sterilised milk would be easily protected against chance of infection if the preventive measures above mentioned were taken.

5. The presence of tuberculous servants should not be tolerated either in the sheds or dairies. Milk pails and cans should be kept scrupulously clean. Of all the measures I have mentioned two seem to me essential: 1. The systematic and periodical inspection of cowsheds and herds for the purpose of weeding out tuberculous animals. To be efficient such an inspection should be thorough and include all the cattle kept within definite administrative areas. For the first year or two compensation should be given to the farmer for losses incurred except in cases of gross or culpable neglect on his part. After this transitional period the presence of a case of advanced tuberculosis in a cowshed should make the owner liable to a penalty. 2. The testing of all cattle brought into, say, a given county, so that fresh sources of tuberculosis should not be introduced. If such methods were adopted it would then be only right to see that foreign dairy produce is not allowed to flood our market unless good guarantees were obtained that proper measures have been taken to safeguard the consumer.

It does not seem probable that general measures of the nature I have described are likely to be carried out in England for some considerable time to come, and probably the work will be left to private initiative. This will render the stamping out of cattle tuberculosis a much slower process than it might otherwise be. It seems to me, however, that work like that done on Lord Vernon's estates if carried out in various parts of the country must ultimately induce a general demand for wholesome milk, which demand will probably be supported by better prices. This demand will ultimately force the farmer to free his stock from all diseased animals, collect the milk and forward it under

[5] The Journal of Comparative Pathology and Therapeutics, June and September, 1897.

Digitized by Google

conditions which will insure the safety of the consumer. At the present time there are only a few who realise the importance of this, and to obtain pure milk the dairy owner must pay higher prices for pure than for impure milk. The consumer should certainly take his share of the expense. Dr. Livesay, who has so ably directed the work done at Sudbury, informs me that a number of farmers on the Sudbury estate have agreed to submit to certain regulations ensuring the exclusion of tuberculosis and purity of the milk. And as compensation the farmer receives 1*d.* more a gallon for this tested milk than he would for ordinary milk. I think the time will come when this inducement will be unnecessary, for the exclusion of tuberculosis will be found to be a source of profit instead of being one of apparent loss, as it seems to be at present.[6]

We have seen that the proportion of cows affected with tuberculosis increases rapidly with age. After the age of three—that is, as soon as cows become useful for breeding and dairy purposes—it is not an exaggeration to say that more than half of them are under the present conditions doomed to become tuberculous. And of this half a certain proportion will rapidly reach the wasting stage, after which they will lose much of their value, if not the whole, as beef producers. Now a young cow with slight tuberculosis properly fattened has a very good value as beef. Were it sold to the butcher at the proper time and replaced by another cow free from tuberculosis the immediate loss to the farmer would be the difference between the price of the beef and of the milking cow. But had the farmer waited longer he would have had a possible loss due to the diminished quantity and lowered quality of milk (for a time the milk production is often not unfavourably affected by tuberculosis) and when ultimately he found it necessary to have the cow slaughtered on account of advancing tuberculosis the value of the cow as beef would have considerably diminished or entirely vanished. In addition to this each tuberculous cow is capable of infecting a number of other healthy animals. Therefore by having his cattle slaughtered as soon as tuberculosis becomes evident the farmer is exposed to an immediate loss which is probably smaller than the prospective loss he would incur did he keep the tuberculous animals.

On the other hand, after having had his tuberculous cattle slaughtered and his stable thoroughly disinfected he may arrange to buy none but cattle which have been certified by competent veterinary inspectors to be free from tuberculosis. He may have to pay a little more for cows bought under these conditions, but the ultimate value of his stock will be considerably increased, for only a small number of his cattle will develop a slight degree of tuberculosis, and this being detected in time will not cause him any serious loss.

In the fight against tuberculosis in cattle by private enterprise unsupported by the State it seems to me that the following lines are clearly indicated:—

1. Healthy cowsheds, well lighted and ventilated, easily cleaned, arranged so as to separate the animals as completely as possible from each other and to prevent the food and litter of one from being contaminated by others. Good water-supply. After discovery of a tuberculous animal thorough disinfection of its stall and if possible of the whole shed.

2. Isolation sheds of the same kind for cattle found to be affected with a moderate or slight degree of tuberculosis.

3. Stalls well isolated from the others might be provided in this shed for animals which have not been tested and have to be kept in quarantine until tested, or better still a special testing shed frequently disinfected might be provided.

4. Immediate slaughter of all cows in an advanced state of tuberculosis.

5. Fattening of cows with moderate tuberculosis; these cows not to be allowed to come again at any time in contact with the healthy ones.

6. Any dairy produce from these tuberculous cows to be sterilised. If butter be made the cream should be treated for some time at 85°, which does not interfere with the making of good butter (Bang). Tuberculous cows should, however, be fattened as soon as possible and their milk used as short a time as possible.

7. Tuberculous cows with tuberculous udders are usually in a state of advanced tuberculosis, but in any case a cow with tuberculous udder should be slaughtered at once.

8. All calves to be fed from the first on sterilised milk. The thoroughly sterilised milk of tuberculous cows might be used for this purpose.

To avoid the other sources of deterioration which I have mentioned:

9. The udder and milkers' hands should be kept absolutely clean.

10. The milk cans or pails should be washed with boiling water or sterilised by steam.

11. This milk should be cooled immediately after being milked and its temperature kept below 40° F. until it is treated in the dairy (by filtration, separation, sterilisation, &c.).

12. Milk which has not been sterilised and which has to be sent by rail from the dairy to a distance should be kept by packing in ice or otherwise at a temperature below 40° F. if possible, until it reaches the consumer. The same precautions with regard to cooling apply to all milk which cannot be consumed within a few hours—say, 8 or 10 hours at the most—from the time of milking.

13. The authorities should be asked to regulate the importation of foreign milk and dairy produce with the view to ensure that the precautions above mentioned have been duly taken to ensure the wholesomeness of these products.

14. The authorities should be asked to find the means to prosecute and punish adequately all kinds of neglect rendering milk dangerous to health so as to place the farms and dairies where proper precautions are taken on a fair footing in the general competition.

[6] Thus in Massachusetts, where an attempt has been made since 1894 to fight tuberculosis in cattle, it has been found that although the preventive measures have not been applied generally and thoroughly enough to insure a diminution in the number of cases, yet cases of generalised tuberculosis have diminished to a considerable extent. Among animals slaughtered after being shown to be tuberculous by the tuberculin test it was found that in 1895 there were 32·6 per cent. of them affected with generalised tuberculosis, in 1896 there were 26·1 per cent., and in 1897 3·5 per cent.

THE PLAGUE IN CALCUTTA.

BY FRANK G. CLEMOW, M.D. EDIN., D.P.H. CANTAB.

MORE than three months have now (August 4th) elapsed since the presence of plague in Calcutta was established beyond a doubt. The disease has in that time shown little sign of becoming widely epidemic or of causing such disastrous havoc as followed its appearance in Bombay, Poona, and elsewhere. The daily number of fresh cases has only on one occasion risen so high as 8, and has usually varied between the limits of *nil* and 3 or 4. The total number of cases appearing in the returns up to, and including, July 31st, 1898, has been 190, and the daily average since the beginning of the outbreak has been less than 2. During the past few weeks there has been a distinct decline even in this small number of cases, and for several days recently there has, so far as plague is concerned, been a clean bill of health. This in itself is most satisfactory and to some extent reassuring for the future. It is obvious, however, that so long as even single cases are occurring they are evidence that the infection has not completely died out or quitted the city, and while that is the case there cannot but be grounds of apprehension as to the course the disease may pursue later, when the advent of the cool season must favour the spread of any remaining infection. For the plague infection made its appearance in Calcutta at a time of year when, if we may judge by the experience of previous epidemics, the seasonal conditions were not favourable to its spread. As a rule, though the rule is not without exceptions, the disease has only become widely epidemic in India in the cool part of the year—that is to say, between the months of November and March. This was the case in the very severe outbreaks in Bombay, in Poona, in Karachi, and in Thana. In certain districts the climax of an epidemic has fallen rather later—in the month of April or even so late as May, when the hot season is fully established. This happened in Surat, where the outbreak reached its highest point in April; in Kolaba, where the mortality was highest between the last week in March and the first week in May; and in the Janjira State, where May was the worst month. In the Navsari division of the Baroda State the main

Digitized by Google

period of the epidemic was from the middle of March to the end of the first week in May. In Cutch Mandvi and in Hyderabad the most fatal period of the outbreak was in each instance in May. It is important, however, to note that in all these epidemics the disease was already established in the town or district some time before the hot season set in and it has not in a single instance happened that the infection, introduced into a new locality so late as the month of April, has started an epidemic in the hot season. The infection was, it is believed, introduced into Calcutta in April of the present year. The behaviour of the disease, therefore, in remaining sporadic throughout the hot and so far throughout the rainy season, is such as might have been anticipated from its behaviour elsewhere, while on the same grounds there is every reason to be prepared for a much more extensive outbreak when the cool weather sets in.

The course of the present outbreak in Calcutta has presented several points of interest. The earliest recognised case of plague occurred on the night of April 16th, 1898, when a sudden death from fever accompanied with swelling of the glands of the left groin took place in Kapalitola, a crowded locality near Bow Bazar, in one of the most insanitary districts of the city. The man's name was Issur Chunder Dey. The clinical history and the post-mortem appearances showed evidence which was regarded by the health officer of Calcutta and by the leading medical advisers of Government as highly suspicious of plague. A most careful bacteriological investigation was made; pure cultures of bacilli were obtained from the bubo and these were found to give all the reactions regarded as characteristic of the plague bacillus. To make assurance doubly sure some of the growths were sent to M. Haffkine in Bombay, and his report confirmed the view that the case had been one of true bubonic plague.

While the case of Issur Chunder Dey derives considerable importance from the fact that it was the first to be diagnosed as plague and that on the result of the investigation of this case ultimately hinged the public recognition by Government of the existence of plague in Calcutta, there is reason to believe that it was not the first case of the disease in this city. 2 days earlier than its occurrence—i.e., on April 14th—2 patients with symptoms characteristic of plague had been admitted to the Medical College Hospital. Both of these patients died. 1 of them, moreover, had been in contact with a patient who had been admitted to the same hospital as early as March 30th, and who had died after an illness which presented many features suggestive of plague. These cases are important as they illustrate the difficulty of assigning a definite date to the appearance of plague in a city, a point to which reference will again be made later. On April 17th 3 other persons were discovered in Kapalitola with symptoms of plague and of these 1 died. A *dome*[1] who assisted at the necropsy on Issur Chunder Dye and accidentally pricked his finger, was the next to sicken and after a long fight for life he ultimately succumbed to secondary pulmonary affection. Before the end of April a total of about 40 cases of plague had occurred and the infection had shown its presence in parts of the city at some distance from the area originally infected. The latter continued to furnish cases, and a second area, around the General Market, began to rival it as a plague centre. Elsewhere only isolated cases were occurring. From that time onwards there has been a slow but steady spread of the disease until there are now only 7 out of the 25 wards into which the city is divided which have not at any time returned a case of plague.

The above facts, so far as they relate to the early cases of the disease in Calcutta (I am indebted to the courtesy of Dr. Nield Cook, the health officer of Calcutta, for many of the details of these cases), were publicly announced by the secretary to the Lieutenant-Governor of Bengal at a meeting of the Bengal Legislative Council held in Calcutta on April 30th. This was the first public recognition of the existence of plague in the city. It will be noted that an interval of fourteen days had elapsed between the date of the first recognised case and the date of the announcement. But it must not be thought that the authorities had in the meantime done nothing to cope with the threatened danger or that the public were ignorant of what had occurred. Both the authorities and the native populace had been equally prompt, though in exactly opposite directions, in taking action on the first breath of suspicion that plague had appeared in the city. The authorities, as already related, took all possible steps to ascertain the exact cause of death in the first case, and without waiting for complete confirmatory evidence—which could only be forthcoming after the lapse of some days—proceeded to act on the supposition that the cause of death had been plague and to take precautionary measures accordingly. The house where the death occurred was thoroughly disinfected, all persons who had been in contact with the patient were removed to a segregation camp, and all articles likely to convey infection were burnt, compensation being paid to the owners. The native populace, on the other hand, the moment it was known that a suspected case of plague had occurred, proceeded incontinently to lose its head and to give way to as violent an attack of panic as has perhaps ever been seen in modern times. This showed itself, as usual in such cases, in a general flight of about one-fourth of the population, in strikes and riots, in the murder of several quite inoffensive persons, and in an attempted reign of terror which fortunately proved abortive. For days together the approaches to the railway-stations were blocked by enormous crowds of struggling natives striving to reach the platforms. The rush to leave the city reached its height on April 29th and 30th, and it has been stated that on those two days alone between 40,000 and 50,000 people left Calcutta. The exodus continued at a slower rate for many weeks, and the estimate generally accepted that some 200,000 people in all fled to the country is probably not above the truth. The wildest rumours were in circulation, attributing the most horrible motives and intentions to Government and particularly to its medical officers. The mildest of these stories was to the effect that the medical men in charge of the plague hospitals were instructed to quietly kill every patient admitted. But no story or rumour was too grossly ridiculous to find ready credence. Unfortunately the native press did little to allay the alarm, and in many instances rather encouraged it by publishing articles which only fanned the flames of panic and disaffection. Interested persons fomented the panic, and the jewellers and goldsmiths are said to have made a rich harvest in the form of bracelets, anklets, and other jewellery purchased from their fellow natives whose sole means of escaping from the city was by converting this portable wealth into money. The scare caused by the fear of plague was succeeded by a second access of panic which may be termed the "inoculation scare." It followed immediately upon the proclamation of Government which aimed at promoting general, but of course voluntary, inoculation with M. Haffkine's prophylactic. It was characterised by another crop of equally wild and gross rumours, and it unfortunately led to some very terrible consequences. Several quite innocent persons were murdered by the mob, and many others were severely mauled merely because the cry had been raised that they were *ticcawallahs*—the native word for inoculators. A little later came the "ambulance scare." The appearance of one of the municipal ambulances in the street was the sure cause of collecting a crowd of excited natives, and on two occasions an ambulance was set upon by the mob and those in charge of it injured, while on one of these occasions the vehicle was completely destroyed and the remains of it were set on fire in the street. At this period patients were removed to hospital under an escort of police armed with *lathies* or long bamboo rods. For a while all of us who were in any way connected with the plague organisation were in more or less danger of personal violence, and it was not safe to go about the city without a revolver. Few Europeans in this city, whether connected with the plague operations or not, failed to provide themselves with this weapon of defence and in a short time it was scarcely possible to purchase a revolver in the whole of Calcutta. This scare came to a climax on Saturday, May 21st, when Dr. Ronald Laing, one of the district medical officers, was attacked by a mob in a native house which he was inspecting. He was compelled to fire his revolver three times, twice with fatal effect, before the mob retired. The incident produced a deep impression and there was a very general feeling that the community owed a debt of real gratitude to Dr. Laing for having by his prompt

[1] *Domes* are natives of very low caste employed in hospitals to do the mechanical part of post-mortem examinations. They often develop great expertness in opening the body and removing the organs. 5 of these poor fellows have unfortunately contracted plague in Calcutta as the result of wounds or scratches inflicted at necropsies on plague patients. The fact is of considerable diagnostic importance, as instances of other diseases being thus contracted by these men, who do not appear to mind making necropsies with open cuts or scratches on their hands, are said to be of very rare occurrence.

action taught the more excitable and turbulent class of natives a much needed lesson. The lesson seems to have been at once taken to heart, for from that time the tendency on the part of the people to interfere with the medical staff in the course of their duties almost at once disappeared. This is not the place to dwell upon the many inconveniences which accompanied this state of panic—the suspension of business, the strikes among labourers of almost every class and the straits to which many people were reduced by the flight of their servants. Anyone who has lived in India and learnt how greatly one's happiness here is dependent upon the faithful discharge of their duties by punkah-pullers, bearers, and table servants, will readily realise the discomfort which a general flight of domestic servants would be capable of causing.

Before proceeding to discuss the further course of the outbreak it is of importance to recall the fact that this is in all probability not the first occasion upon which the plague infection has made its appearance in Calcutta in recent years. Very shortly after plague broke out in Bombay in the autumn of 1896 a group of cases occurred in Calcutta which gave rise, it is said, at the time to considerable controversy and no little alarm. The cases are fully described in the Annual Report of the Health Officer of Calcutta for the year 1896-97.[2] Dr. Simpson, the late health officer, there writes that, as a rule, epidemic diseases prevailing in Bombay sooner or later find their way to Calcutta, and that "in October, 1896, a case of glandular sickness with fever occurred in Howrah in a patient who had arrived from Bombay." Howrah is a separate municipality, divided from Calcutta only by the River Hooghli. The case was regarded by Dr. Simpson as a case of pestis ambulans, but the Medical Board[3] investigating the case later came to the conclusion that there was no evidence to consider this a case of true bubonic plague. Then there cropped up (the report continues) "a group of similar cases, one of which was fatal, each with fever, glandular enlargements, and presenting bacilli in the blood." Then a case of bubonic fever occurred in a child named Giga and in the same house a sickly-looking rat was seen. The rat was in a dazed condition and was easily caught and killed. On examining this animal "the glands of the left groin were found to be enlarged, congested, and agglutinated together. The internal organs were generally congested; diplo-bacteria were found in the blood and internal organs and cultures from these gave growths resembling specimens of plague bacilli in rats received from Bombay. Healthy rats were examined, but no bacilli were found in their organs." It is of interest to note that the occupants of the house where this rat was found were Marwaris, who received goods, clothing, and yarns from Bombay. A week later it was reported that an unusual mortality among rats was occurring in two grain shops in a street called Burtolla-street. As many as a hundred dead rats were found in one day in one shop alone. Some of these animals were examined and exactly the same pathological changes were found in them as have just been described above. In both shops "the floors were dug up, the place flooded with disinfectants, and any rats found were killed, after which no further cases occurred. A few sick rats were found in adjoining houses and these houses were also thoroughly cleansed and disinfected and the rats destroyed."

Reviewing these facts there seems to be little room for doubt that so long ago as October, 1896, the plague infection was introduced into Calcutta; but, whether as the result of the measures taken or from the conditions then met with proving unfavourable to its spread, there was no extension of the disease. If the infection which thus manifested itself for a brief period was indeed the true plague infection (it is right to recall that many highly qualified observers did not and do not regard it as such) the fact that it did not extend is a remarkable one; and it is the more remarkable in that the time of year at which it appeared was the time of year when, as has been already shown, plague, if introduced into an Indian city, is most likely to spread and become widely epidemic.

To return from this digression. The further course of the present outbreak has been as follows. After a marked rise in the number of cases at the end of April (17 fresh cases occurring in three days) there was a sudden pause and in the first week of May only 4 fresh cases were reported. The following table completes the statistics of the outbreak:—

Week ending	Number of fresh cases reported.	Week ending	Number of fresh cases reported.
May 7th	4	June 25th	19
,, 14th	8	July 2nd	23
,, 21st	10	,, 9th	17
,, 28th	9	,, 16th	12
June 4th	15	,, 23rd	4
,, 11th	16	,, 30th	4
,, 18th	19		

These figures, it will be observed, show a distinct rise to a small maximum followed by an equally distinct and more rapid fall. They are, however, obviously too small to lead to any conclusion based solely upon them. It may or may not be of significance that the highest part of the small curve formed by these figures fell in the weeks immediately following the breaking of the monsoon and setting in of the rainy season. June 15th is regarded here as the average date when this looked-for event may be expected to happen, and this year it came very near to that date. Judging from the present season it does not seem to be very easy to fix an exact date for the commencement of the rains. There had been many heavy showers at intervals throughout the great heats of May. Towards the second week of June there was a gradual but distinct change in the weather; the clouds gathered more and more ominously each day and the showers became more frequent, until by about June 16th or 17th it was very generally admitted that "the monsoon had broken" and the long rainy season fairly begun. While on the subject of weather it should be added that the hot season this year in Calcutta was, in the opinion of most people, an exceptionally cool one. The showers in May already referred to certainly did much to relieve us from the burden of heat and glare of sun which at times during that month had been very trying. Calcutta is far from being among the hot places of India; its average temperature is a moderate one when compared with that of such furnaces as Jacobabad or Mooltan, where the thermometer in the hot season may remain for days together above 120° F. in the shade. From personal experience I can speak only of the second half of the hot season in Calcutta. During that period I did not see the thermometer rise on any occasion above 96°, though on one excessively close day the return from the meteorological office recorded 99° in the shade. But, though the climate of Calcutta is not an excessively hot one, it is an excessively moist one. The coefficient of humidity, even in the hot and dry season, is seldom less than 75, and is more often between 80 and 90. Since the rains have set in there has been an appreciable and welcome change of some 10° in the height of the thermometer, which instead of averaging as before between 90° and 95° now usually stands between 80° and 85°.

The plague infection made its appearance in Calcutta in the earlier half of the hot season. From the moment of its appearance two important problems presented themselves for solution: firstly, whence had the infection come? and secondly, having come, what would its behaviour be? The first problem has up to the present proved insoluble. The earliest patients, so far as could be ascertained, had had no communication directly or indirectly with Bombay, Hong-Kong, or any of the other places where plague was or had been epidemic. There is, however, some interesting evidence, which will be discussed later when speaking of the disease in rats, tending to show that the infection may have been brought to Calcutta by ships trading from some infected port. The second question has been partially answered: the infection has spread in the course of rather more than three months to nearly all parts of the city; worse in some parts (particularly Wards 8, 10, and 13, all more or less central wards), more slight in others. In five of the twenty-five municipal wards into which the city is divided there has been only a single case of plague reported, while seven (all with one exception either suburban wards or wards mainly inhabited by European residents) have been fortunate enough to escape altogether.

A further and equally important question remains for solution, What will the disease do when the cool weather sets in and conditions arise which are known to be favourable to the extension of plague? Will it become widely epidemic

[2] A still more detailed account of these cases will be found in Parliamentary Paper, C. 8368: "Papers relating to the Outbreak of Bubonic Plague in India up to March, 1897."

[3] The Medical Board was appointed in October, 1896, to supervise all plague measures in the Bengal Presidency. It was the predecessor of the present Plague Commission appointed last November.

in Calcutta as it did in Bombay, Poona, and elsewhere? will it disappear altogether? or will it remain as at present, the cause of only occasional sporadic cases?

In this connexion a comparative study of the rapidity with which the infection of plague in past epidemics has gained a hold upon a given community may prove interesting and may throw some light upon the question at issue. It may be stated in general terms that all epidemics of plague commence with a period in which the disease presents itself in isolated, sporadic cases. This period is of uncertain length and may vary from a few weeks up to many months. To take examples, it will probably be admitted that the three greatest epidemics of modern times have been the Great Plagues of London in 1665–6, of Marseilles in 1720–1, and of Moscow in 1770–1. The recent outbreaks in Bombay, Poona, and Karachi, severe as they have been, cannot be compared with these in regard to the number of persons attacked, but they are of more importance in the present connexion from the fact that they occurred recently and in India, and may therefore be included in this rapid survey.

In the Great Plague of London the earliest known case of the disease is supposed to have occurred at the end of November or beginning of December, 1664, but it was not until the end of May or beginning of June, 1665, that the weekly return of cases of plague began to be seriously high, and the main period of the epidemic was during the summer and autumn of that year.[4] The presence of the plague infection throughout the winter of 1664–5 is evidenced by the appearance of "plague" in the mortality returns of several parishes and probably also by the unusually high death-rate which prevailed in London throughout the winter. In this great pestilence, therefore, the sporadic period preceding the great epidemic outbreak was probably of about six months' duration. In the Great Plague in Marseilles this period seems to have been shorter. The infection is supposed to have been brought to the city by a ship from Syria which arrived at Marseilles on May 20th, 1720. Cases of plague had occurred on board, and on June 22nd cases began to occur among the porters employed in unloading the ship, and very shortly after the plague seems to have become widely epidemic.[5] In the Great Plague of Moscow the early course of the epidemic was remarkably similar to that of the Great Plague of London. In Moscow the earliest cases occurred in October or November, 1770, and it was not until the following spring that the disease began to be extensively epidemic. Here, as in London, cases of plague occurred throughout the winter and there was a distinct rise in the general mortality.[6]

With regard to the first appearance of plague in Bombay in 1896 some evidence has been recently published, from which it would appear that the sporadic period was of much greater length than has been hitherto supposed. In the extremely valuable report upon Plague in India, issued by Government in April last, it is written[7]: "Several circumstances point to plague having prevailed in Bombay for some time before its existence was recognised. In August cases of fever with glandular swellings had been attended by several medical practitioners, cases of fever accompanied by pneumonia had been reported to the executive health officer, and a death was actually registered on the 31st August as due to bubonic fever. These circumstances failed to arouse an alarm of plague, as a type of fever with glandular swellings has, it is said, been for years known in Bombay. Again, it is stated by Mr. Snow, the Municipal Commissioner, that 'when plague broke out, several native practitioners of the first standing acknowledged that from the end of the hot weather in May onwards they had come across several cases of peculiar fever which entirely puzzled them and usually ended fatally. It does not, however, appear that the bubonic swellings in such cases were apparent in a marked degree, and little further thought appears to have been given to the matter, which is no wonder considering the various obscure forms of plague noticed in the epidemic.'" The great epidemic rise of plague in Bombay began at the end of September. If the cases just referred to were in truth early cases of plague, the sporadic period of the disease may be said to have lasted for four months. An increased mortality rate began to prevail in the city from the end of August. In Poona "the infection appears to have taken hold of the city early in January. It spread steadily throughout January and February, and culminated in the middle of March." In Karachi cases of plague occurred at least as early as the beginning of December, and the great epidemic rise began in the month of January.

To sum up, in at least 3 of the 6 epidemics here briefly reviewed the disease remained in a sporadic form before it became widely epidemic for a period to be reckoned by months. It should, however, be added that in each of these epidemics this period was marked by a more or less striking rise in the general mortality. This has so far not been the case in Calcutta, and it is perhaps the most hopeful feature in the present outbreak that the general mortality of the city has remained comparatively low throughout; and even when allowance is made for the greatly reduced population as a result of the general flight there does not appear reason to believe that there has been any great increase of mortality among the remainder. Unfortunately, the mortality statistics of any Indian city are open to many sources of vitiation. Bodies are frequently burned or buried without any medical certificate as to the cause of death. The returns from the burning *ghâts* and cemeteries are acknowledged to be never more than approximately correct, and there are strong grounds for suspicion that the rupee is quite powerful enough to secure the disposal of a body without any return or entry of it at all being made. It is therefore more than probable that many cases of, and deaths from, plague have occurred unknown to the authorities. There are other than *à priori* grounds for this belief. For example, attention has recently been called to the extraordinary predominance of males over females in the returns of cases. The proportion of the sexes in the general population of Calcutta was, according to the census return of 1891, as follows: males, 447,000; females, 235,000, or about 53 females to every 100 males. There are many reasons[8] for believing that this proportion is much below the truth and that the true ratio of the two sexes is much more nearly one of equality than these figures express. But in the 190 plague cases which have appeared in the returns the proportion of males to females has been immensely higher. Thus among Hindoos the distribution of the sexes has been 87 males and 18 females; among Mohammedans, 48 males and 8 females; and among Eurasians, 13 males and 11 females. Expressed in percentages, there have been for every 100 male cases, among Hindoos only 20 female cases, among Mohammedans only 17, and among Eurasians as many as 91. So far as is known of the general mode of spread of the plague infection there does not seem any very good reason to suppose that men are more exposed to the infection than women. On the contrary, since plague is generally regarded as a "house disease," and one in which the soil contains and conveys the infection, it would appear probable that women in India are more exposed to the infection than men; for not only are they more confined to the house, but one of their most constant occupations appears to be the cleansing of brass and other vessels with earth scraped from the floor of their huts or from the road outside. There is therefore constant opportunity in the case of Indian women to come in contact with the plague infection; and unless there is some very excessive degree of susceptibility to plague in men over women, the figures just quoted may, with much reason, be held to point to concealment of a number of cases occurring among females. No such excessive degree of susceptibility has been proved elsewhere and, moreover, it will be observed that among Eurasians, against whom no charge of concealment of cases could possibly rest, the cases have been almost equally divided between the two sexes.

In discussing above the early history of the epidemic in Bombay reference was made to the statement that a type of fever with glandular swellings had been known for years in Bombay. This raises a point of no little interest and

[8] "According to the census report of 1891 to every 1000 males there are returned only 958 females [i.e., for the whole of India]; and the tables show that there are in the country fewer females than males to the number of, speaking roundly, 6½ millions. The deficiency is greatest in the Punjab, N.W. Provinces, and Rajputana. In Bengal, Madras, and Upper Burmah, however, females are in excess to the extent of something under three-quarters of a million. The conclusion arrived at with regard to the deficiency of females is that it is to a large extent due to deliberate concealment and deliberate omission from the census returns." *Vide* editor's footnote on p. 213 of the last edition (1897) of that wonderful storehouse of information, "Hindu Manners, Customs, and Ceremonies," by the Abbé Dubois. In 1896 the proportion of registered female births to registered male births in Calcutta was 87·5 to 100.

importance in connexion with the present outbreak in Calcutta, for here the same assertion has been widely made, and during the early weeks of the outbreak there were many practitioners of high standing and repute who maintained the view that the cases returned as plague were not cases of plague at all, but cases of the endemic fever with buboes. Almost without exception these gentlemen have since admitted that, in view of the clinical character and high mortality of the recent cases, they have rightly been regarded as cases of plague. The occurrence of this endemic disease is, however, of importance, as it must add one more difficulty in the way of fixing an exact date for the first case of an epidemic of plague, to which reference was made earlier in this paper. The evidence for the existence of such a disease is conclusive, although it is a remarkable fact that at one of the largest of the Calcutta hospitals no such cases are ever seen.[9] It is based upon the assertion of many practitioners in Calcutta that a certain number of cases with these characteristics are met with in general practice every year, and upon statistics of a similar disease among English troops in Fort William, where every year an average of between 30 and 40 cases of fever with glandular swellings occurred in the years 1890–6 inclusive.[10] No published description of this disease appears to exist, but, so far as may be gathered, it would seem to differ from plague in its being altogether of a milder character, in its low rate of mortality, in the fact that suppuration of the glands is the exception rather than the rule,[11] and in the absence of any concurrent disease in rats. The bacteriology of the malady has not, it would seem, been studied.

Frequent reference has been made in the course of this paper to the appearance of a disease among rats preceding and coincident with the appearance of plague in man. It must now be accepted as one of the established facts of medicine that in almost all outbreaks of human plague rats are affected by a similar disease both before and during the epidemic. The evidence that the two diseases are the same is of exactly the same character as that which has established the identity of human and bovine tuberculosis, and there seems to be but little more reason for suspension of judgment in the one case than in the other. It may therefore be accepted that plague in man and plague in the rat are, as far as our present knowledge of the two diseases goes, one and the same disease. Evidence has been published[12] that the disease may attack other animals than the rat, such as dogs, pigs, pigeons, and domestic fowls. I have no personal knowledge of such an occurrence (with the exception of a very doubtful case in a dog),[13] and the present notes are therefore confined to the disease in rats.

There is, as already stated, some interesting evidence pointing to the possibility that rats were the means of introducing the plague infection into Calcutta. Before the date of the first recognised case of plague in man intimation was received at the Health Office that a number of dead rats had been found in an office situated near the river; and a little later other dead rats were found in a street close to and parallel with the river and in the warehouses of a shipping company near to the wharfs where ships unload. The occurrence seems to have been so unusual as to have at once attracted attention and the premises were cleansed and disinfected. Some of these animals were examined at the municipal laboratory and cultures of the plague bacillus were obtained from them. Ever since the beginning of the outbreak dead rats in large numbers have been found in various parts of Calcutta but more particularly in and near houses where cases of human plague have occurred. In a large city like Calcutta a certain number of dead rats will always be found, but during the past three months the number has been unusually large and there can be no question that this has been due to the occurrence of a plague epizoötic among these rodents. Several specimens examined at the municipal laboratory were found to present pathological changes characteristic of plague, and moreover pure cultures of plague bacilli were obtained from the enlarged glands and other organs. The following incident came under my own immediate observation. A death from plague occurred on certain premises in British Indian-street. Previously a number of dead rats had, it was ascertained, been found on these and on adjoining premises, and several cases of plague had occurred in the immediate neighbourhood. The patient had died at 3 A.M. on June 15th, and at 7 A.M. I saw the body, which was still lying in the outhouse or *godown* where death had occurred. The post-mortem examination revealed all the pathological changes characteristic of plague, and I was moreover able to obtain pure cultures of the plague bacillus from both the bubo and the liver. There was therefore no doubt as to the cause of death. At the time of inspecting the body I had observed that the big toe of one foot had been half eaten away by rats. During the following week or two there was a marked increase in the number of dead rats found on the premises where the man had died and on the adjoining premises. Some dazed and sickly-looking rats, which showed evident signs of severe illness, were also seen in an adjoining house. Unfortunately these facts did not come to my knowledge until later, and it was therefore impossible to obtain any of the bodies for examination, but the facts left little doubt in my mind that the rats had died from plague, and that in some at least this result was brought about by their fatal feast off the tissues of the dead man's toe.

A few words may be added as to the mortality of the plague as it has shown itself in Calcutta. Among male Hindoos the proportion of reported deaths to reported cases has been 86·2 per cent.; among female Hindoos, 72; among Hindoos of both sexes, 84; among male Mohammedans, 85; among female Mohammedans, 88; among Mohammedans of both sexes, 86; among male Eurasians, 54; among female Eurasians, 73; among Eurasians of both sexes, 63; among males of all classes, 83; among females of all classes, 76; and finally among persons of all classes and both sexes, 82 per cent. The figures upon which these percentages are based are in many instances, particularly in the female groups, too small to permit of any sweeping conclusions as to racial or sexual susceptibility to the plague poison, but attention may be called to the remarkably low mortality among Eurasians. A similar observation was, it will be remembered, made in the epidemic in Hong-Kong. The mortality among the natives, both Hindoo and Mohammedan, as expressed by the above figures, may possibly be above the truth, as cases which recovered are more likely to have been concealed than cases which died. The only European (a male) who contracted the disease recovered. Of other nationalities, two Chinese, one Burmese, and one Jewess caught the disease, and in each case it proved fatal.

Calcutta.

9 I am assured that this is so by the medical officers of the Medical College Hospital.

10 Parliamentary paper C. 8386: Papers relating to the Outbreak of Bubonic Plague in India. The statistics are furnished in a statement by Surgeon-Lieutenant-Colonel W. Allan May, in charge of the Station Hospital, Calcutta, dated October 22nd, 1896. It had been suggested that the cases suspected to be plague then occurring in Calcutta (*vide supra*), and some cases of glandular fever in men of the Shropshire Regiment (recently transferred to Calcutta from Hong-Kong where they had been on plague duty) might have some connexion. The statistics here referred to rendered this view untenable.

11 In the Parliamentary paper already quoted from will be found a reprint from the *British Medical Journal* of an article by Fleet-Surgeon Charles C. Godding on "Non-Venereal Bubo," from which it appears that a bubonic disease with fever is common in the navy on certain stations, a yearly average of 733 cases occurring out of a yearly total of 56,180 men. The disease would, however, appear to differ from the one under consideration in the more frequent occurrence of suppuration. May not the habit of sailors of going about barefooted afford an explanation of the occurrence of these buboes, which are "invariably inguinal"?

12 Dr. Cantlie and Dr. Lowson at the Epidemiological Society of London in December, 1896. THE LANCET, Jan. 2nd and 9th, 1897.

13 A. B. was attacked with plague on June 30th, 1898. He recalled the fact that two or three weeks before (he could not fix the day) his little dog had brought a dead rat and placed it on his bed. A day or two later the dog had seemed unwell, but it had rapidly recovered; it was not known whether any glandular enlargement had occurred. The patient had touched the rat in removing it from the bed; but in view of the facts that over a fortnight elapsed before he himself sickened, and that he lived in an infected area, there seems no reason to believe that this was the particular source from which he contracted the infection.

NOTE ON A CASE OF SATURNINE AMBLYOPIA.

BY CHARLES BELL TAYLOR, M.D., F.R.C.S. EDIN.,
SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

A WOMAN, aged twenty years, single, consulted me on account of failing sight in May of the present year. There was no evidence on superficial examination of inflammatory affection or organic change, but the ophthalmoscope revealed white atrophy of the left optic disc and I found on testing vision marked central scotoma in both eyes, notwithstanding that the right papilla was apparently normal (amblyopia

Digitized by Google

without tissue change). I diagnosed drug amaurosis and detected in the urine traces of lead which I then ascertained she had been taking in ten-grain doses nightly in the form of emplastrum plumbi for upwards of three weeks. Under treatment the right eye recovered perfectly, but the left, although it has improved considerably, is still very defective and likely to remain so.

The power of certain drugs to produce definite tissue change in the optic nerves (axial neuritis) is a curious property possessed by a variety of substances—alcohol, tobacco, lead, and other metals for instance, as well as quinine, salicylic acid, santonin, bisulphide of carbon, and various coal-tar products. Of these, according to my experience tobacco is the most frequent cause of impaired sight, not only on account of the nicotine which it contains and which in its natural form blinds the horses which graze upon pastures where tobacco is grown, as in some parts of New South Wales, but also on account of the pyridine, viridine, carbolic acid, and marsh gas which are set free when it is smoked. Alcohol probably comes next, while saturnine amblyopia among the workers in lead factories has been known for centuries. The lead may enter the system either with articles of food or drink, the workmen in the former case neglecting to wash their hands, or through the skin by means of hair dyes and cosmetics, or by silk threads which are weighted with sugar of lead and bitten instead of cut by those who use them. In my case the patient, finding herself pregnant, took diachylon in order to procure abortion, with no other effect than to cause blindness in one eye. That this should result in four weeks' time without other symptoms of plumbism, colic, leadline on the gums, palsy, or wrist-drop is indeed singular if not unprecedented.

With regard to treatment in such cases iodide of potassium should be given in large doses, the patient should use baths of sulphuret of potassium, take sulphate of magnesia, mercury, and pilocarpine, while the affected nerve should be galvanised with the continuous current, about 2 milliampères to each temple daily.

Nottingham.

STRANGE SUCCESSION OF FRACTURES IN A COLLIER, WITH REMARKABLE COINCIDENCE IN TIME OF OCCURRENCE.

BY D. T. RICHARDS, M.D. GLASG.,
SURGEON TO RISCA COLLIERIES.

As might naturally be expected from his hazardous occupation the collier is frequently injured by accidents underground. But the following particulars deserve, I think, a space in THE LANCET because of the strange series of fractures sustained by the man himself and his near relatives, as well as the remarkable coincidence in the date of their occurrence as far as the patient himself is concerned.

A man, aged forty-four years, short and well built, was first attended by me on August 26th, 1890, for a compound fracture of the left leg, resulting from a portion of the roof or top falling and striking him while following his employment in Risca Collieries. After being brought out and conveyed on a stretcher to his home on the hill-top, a distance of about three miles, a journey by no means easy to bear by a man with a fractured leg, I found on examination a crescentic wound nearly 3 in. long on the outer aspect of the middle of the left leg, and well peppered over with coal-dust. In spite of the temporary splints and scarf tourniquet applied by his fellow workmen considerable hæmorrhage had occurred, no doubt aggravated by the long, rough journey over an uneven road and up the hill. An anæsthetic was given and the tibia and fibula were found to be fractured near the same level, about half-way between the knee and ankle, and detachable sequestra were removed. After free ablution and cleansing with carbolised water and the limb being brought to a good position iodoform gauze was applied and the leg put up in a modified box-splint. For some hours, the patient felt easy, but during the night he was sick and the leg was painful, which kept him from sleeping. When seen next morning his temperature was 102° F., the pulse was 112, and the tongue was covered with dry white fur. After a grain each of calomel and opium he felt easier and slept. Suffice it to say the patient made an uninterrupted recovery and was able in about six months to resume his work as a collier underground.

The patient's previous history, told by himself and corroborated by others, is very remarkable. With the exception of an attack of typhoid fever, which he had when eighteen years of age, and two or three attacks of quinsy subsequently, he had not suffered bodily in any way. He was always very temperate and for about eighteen years a total abstainer. But his misfortunes in the mine were many and are remarkable from the fact that they all happened on the 26th day of August. Here is his record. At the age of ten years he fractured his right index finger. It happened on August 26th. When thirteen years old he fractured his left leg below the knee through falling from horseback, also on August 26th. When fourteen years of age he fractured both bones of the left forearm by stumbling, his arm striking the edge of a brick (August 26th). In another year, on August 26th, when fifteen years of age, he had compound fracture of the left leg above the ankle by his foot being caught under an iron rod and his body falling forwards. Next year, again on the same date, August 26th, he had compound fracture of both legs, the right being so severely crushed that it had to be amputated at the lower third of the thigh. This was caused by a horse, hitched to a tram of coal, which, running wild underground, caught him in a narrow passage, crushing both legs severely. After this he did not work on August 26th for 28 years, and little wonder, but in the year 1890 he forgot his fateful day and went to work, with the result that he sustained the compound fracture which I have mentioned in the beginning. After this he has studiously avoided working on August 26th, though never missing work at other times.

The patient's father is living, aged seventy-nine years, and has never had a severe injury. His mother died at the age of seventy-nine years. When aged sixty years she had compound fracture of the leg below the knee through being run over by a truck. Recovering, she enjoyed good health for fourteen years, when the old wound reopened and discharged small pieces of bone. The wound remained open for about a year, when under treatment it healed. From this time her health failed and her death, which occurred soon after, was attributed to the healing of the wound. The patient had no brothers, but his only sister, when ten years of age, fractured both bones of the forearm, refracturing the same in about three weeks by falling with her arm under her. One cousin had an arm amputated at the shoulder for injury and another cousin had a severe compound fracture of the leg, while a third had fracture of the leg from which he died. Of three paternal uncles one had his leg amputated for injury underground.

Risca, Mon.

SARCOMATOUS DEGENERATION IN AN UNDESCENDED TESTICLE; CASTRATION; RECOVERY.

BY JAMES R. WALLACE, M.D. BRUX., F.R.C.S. IREL.,
FORMERLY RESIDENT SURGEON TO THE MEDICAL COLLEGE HOSPITAL, CALCUTTA.

AN Anglo-Indian, aged twenty-five years, short, thick-set, and of good constitution, was born a cryptorchid, his left testicle having remained undescended from birth. There was always, as long as the patient could remember, a "lump" in the left groin. It had remained absolutely painless till about four months previously to his consultation with me, when he observed occasional acute pains in the swelling and a frequent sense of nausea. In a few weeks the pain became worse, the swelling more enlarged, and there was persistent vomiting, which confined him to his bed for a few days. The symptoms subsided, but with the resumption of his duties there was a recurrence of suffering. When I first saw him, on March 22nd, 1898, the lump in the groin was hard, tender, and non-fluctuant. The slightest pressure upon it induced nausea. Sulphate of magnesia with tartar emetic in small doses internally, the application of belladonna and glycerine to the swelling, with rest in the bed, gave complete relief

Digitized by Google

and for three weeks the patient was able to go about his work. On April 25th he had a recurrence of all the bad symptoms above described, but finding that the slightest exertion was attended with a return of suffering he was advised to undergo castration of the undescended testicle. Accordingly on April 29th he was placed under chloroform by Dr. William Coulter. I cut down upon the testicle, doing the bulk of the dissection with the handle of my scalpel. The main vessels leading to the tumour were ligated and the mass was cut off above the ligature. All bleeding points were quickly secured by pressure forceps so that the patient did not lose more than half an ounce of blood during the operation. The wound cavity was insufflated with iodoform and boric acid, a drainage-tube was inserted, and the incision was closed by horsehair sutures. Boric gauze dressings were applied and changed on the second day, when also the tube was removed. The subsequent progress was most satisfactory. During the operation I had the assistance of Mr. Arnold Caddy.

Remarks.—This case is interesting from the diagnostic value of the reflex testicular vomiting as the characteristic sign of the disease present. On cutting into the testicle after removal it was found to have undergone purulent inflammatory change, and as the structure of the mass seemed very much altered pathologically it was sent to Surgeon-Major J. F. Evans, the pathologist to the Calcutta Medical College, who reported on it as follows: "I find the tumour which you sent me on April 29th to be a round-celled sarcoma, with practically no trace remaining of the glandular structure of the organ in which the new growth arose. There is some evidence of inflammatory change and of hydrocele having occurred prior to the formation of the growth."

Calcutta.

RE-BREATHED AIR AS A POISON *PER SE*.

BY JOHN HARTLEY, F.R.C.S. ENG.,

SURGEON TO THE DARLINGTON HOSPITAL; LATE SENIOR DEMONSTRATOR OF ANATOMY, MIDDLESEX HOSPITAL MEDICAL SCHOOL.

THE noble work which has been, and is still to be, done by the bacteriologist can never be over-valued or over-applauded, but I think our attention is apt to be so absorbingly fixed on the ever-increasing cloud of organisms that we are somewhat in danger of losing sight of the effects of those gaseous poisons which are so prone to accumulate very literally under our noses in the present state of "civilisation" and over-crowding. The "Fresh Air Treatment of Consumption," which has been so lately hall-marked in a manner absolutely unprecedented, appears to be made up of three essential factors: (1) the discontinuance of the supply of bacilli from without; (2) the supply of an abundance of nutritive material to the tissues; and (3) the supply of an abundance of fresh air uncontaminated by the products of respiration. This seems to mean that the tissues if not too enfeebled may be trusted to deal with the bacilli already present if their metabolism is kept going at high pressure. Fresh air is now the "official" remedy in the treatment of tubercle. Why is it so ignored in the case of other diseases? We are told that the expired air of the phthisical patient contains no bacilli, so that apparently re-breathed air is not forbidden to him on account of these. Does the pneumonic or bronchitic breathe out bacilli? If so he would seem to require airing more than the phthisical patient; and if he does not, what then? A rise of temperature or the presence of bronchitis or of a patch of pneumonia in the phthisical patient is, I am told, no bar to his being officially aired. Has the pneumonic or bronchitic no need of special ventilation because his microbe is of a different breed?

Within the last three years or so I have known a severe case of double pneumonia (probably influenzal) treated by a specialist, without protest, in an unventilated little room with closed door and window and no chimney but with a paraffin lamp burning day and night to keep up the temperature. When I remember this and contrast the treatment of pneumonia by one eminent authority with the treatment officially recommended for phthisis by the other eminent authorities with the weight of the Colleges at their back, am I, a poor, unscientific, general practitioner, to be blamed if I find it, like Dickens's millband, "awe a muddle"? And it is with the greatest humility that I venture to suggest it is possible when the air was created that it was intended not only for phthisical patients or patients suffering from pneumonia but for *all*—diseased and healthy alike—and that it is still the natural medium in which the poisonous products of tissue metabolism excreted by the lungs are further broken down and rendered harmless. With even more humility I suggest that it is a work of supererogation to heat air twice over—since everyone has, I suppose, a fairly good heating apparatus inside; that, in fact, so long as the patient's surface is kept warm it is of no consequence whatever whether the air he breathes, provided it be fresh, is at freezing point or the traditional 65°.

Dr. A. Ransome has done great service not only by his onslaught on "air sewage" but also by his coinage of the term. For a thoroughly good opprobrious epithet resembles a good wall-poster in its power of arresting and enchaining the attention of the many. It was long ago pointed out that certain constituents of expired air are intensely powerful nerve poisons. Whether sewer gas has been actually proved to contain similar toxins I am sorry to say I do not know, but having regard to its largely similar origin from decomposing proteid, though coming through a different channel, one can hardly doubt that it is so. These considerations should surely make us look on re-breathed air and sewer gas, not as mere carriers of accidental poisons, such as influenza and pneumonia and the like, but as *poisons per se*, and I wish to be allowed to record a few very imperfect observations made by myself during some years past chiefly on the subject of re-breathed air, with certain inferences which I think tend, however feebly and imperfectly, to show that the poisons we expire have *per se* very definite effects on tissue metabolism and need not a mere perfunctory admixture with fresh air but very large and very continuous dilution before they are rendered innocuous—that is to say, innocuous to *all;* for while some persons appear to be almost immune others seem intensely susceptible.

The first observation I will allude to was made in the autumn of 1896, in cool weather. I had to take a long night journey by rail after a long and hard day's work. The train was full and the compartment I entered was close, so, as I was tired and fagged, I sat in the corridor by an open window, well rugged up, throughout the journey. The compartment was completely shut off from the corridor by a glass door and windows, through which I could freely inspect its occupants. Two remarkably fresh-complexioned, wholesome-looking young fellows got into the compartment at York. They formed a remarkable contrast to the pallid and fagged-looking travellers already there. The windows and ventilators were carefully closed, and the new-comers, with the rest, settled off to sleep and slept soundly for nearly four hours, with the exception of a few minutes' interval at Grantham. When aroused on nearing London they, like the other occupants of the compartment, were haggard and leaden-hued, their fresh colour was entirely gone, and they looked and moved as if exhausted. I examined my own face in the lavatory mirror at the beginning and end of the journey and could see but little alteration in my colour, if anything it was rather improved by the end of the journey, and though I had slept little I was decidedly less tired than when I started. There had been but little smoking in the compartment, every one had slept too soundly. The gas lamp, I noticed, was so fitted that the products of combustion escaped directly into the outer air; the hot-air apparatus had not been started. It seemed to me that the change in the appearance of the two young fellows must be due entirely to the effects of re-breathed air. The inferences seemed to be these: the leaden grey hue was a mixture of pallor and blueness, pallor owing to contracted arterioles, blueness due to dilated venules, whether from peripheral vaso-motor changes primarily or from central changes beginning in the heart or lungs I cannot say, but I am inclined to believe peripheral, or why do so many people get clammy feet and hands in a close room? Carbonic acid may have had something to do with it—I think not much. The colour was more pale than blue—i.e., grey; and a similar though less marked change may be seen in the faces of some of the members of most congregations any Sunday towards the end of the service even though the air space is large enough to put carbonic acid poisoning out of court.

Dr. Lauder Brunton a good many years ago recorded a

Digitized by Google

most interesting experiment designed to show the antagonistic effects of muscarin and atropin. The thorax of a curarised dog was opened and artificial respiration started; a small quantity of muscarin was then injected with the result that the right heart and lungs became greatly swollen and engorged while the left side of the heart became almost empty. Atropin quickly caused both sides to return to their usual size and the lungs returned to their usual colour. I believe no mention was made of the state of the peripheral circulation; but I have often thought that re-breathed air must contain a poison similar in its effects on the peripheral circulation to those recorded by Dr. Brunton of muscarin on the central.

Some years ago a patient of mine, who certainly had all the surroundings which can render a man liable to sewer-gas poisoning, was seized with acute illness. He lay on his back with limbs outspread, a leaden-coloured face and clammy skin, with sighing respirations, a small, quick, feeble pulse, great restlessnes, and complaining of "awful" flatulence, begging me to relieve the "awful" distension of his abdomen. (These were his expressions.) There was *no* distension and *no* tympanites. His symptoms were slowly relieved by large doses of atropin subcutaneously and next day he was better, his colour was natural, and the sense of distension was gone, but his abdomen was very tympanitic. I thought the sense of distension complained of was due to overfulness of the abdominal veins, not to distension of gut—that he was, in fact, bleeding almost to death into his abdominal veins. When somewhat better he went to Norway and kept well there except for two slight attacks. The first occurred at a primitive inn where the contents of a cesspool in the closed courtyard were carried through the house in buckets on the night before the onset of his illness; the second attack, a very slight one, occurred on a return visit to the same inn. This is probably an unjustifiable digression, but the effects of sewer-gas on myself are, so far as sensations go, almost identical with those of re-breathed air.

The second case occurred early in 1897. I was asked to see a woman, aged about forty-eight years, who had been treated in a neighbouring town for many weeks for bronchitis and asthma following influenza. She had relapsed about a week when I first saw her. She was then sitting up in bed; her face was leaden-coloured, her skin was clammy and sweating, with a feeble, quick pulse, and the heart sounds were indistinguishable owing to wheezing; there was some crepitation at the bases. The temperature was about 101° F. The weather was cold, but after wrapping her up, with a hot bottle to her feet, the window was well opened. Her colour improved in a few minutes and the sweating ceased soon after. But it and the blueness returned if the window was shut for any time. It was directed to be kept open night and day, and I could see from my house that this order was carried out. Although on one night the thermometer showed 14° F. of frost the chest was clear of noises and she was convalescent in eight days. If fresh air needs warming she ought to have died.

The next case was that of a slight but healthy-looking young fellow, aged twenty-two years, who was admitted into the Darlington Hospital under my care in September, 1897, suffering from a strangulated congenital hernia. An operation for radical cure was performed in the usual way. The hospital was then full, and the ward in which the patient lay was in my opinion decidedly stuffy, though in other respects its sanitation was excellent. The wound gave no trouble, but the patient became very restless, with grey face, foul tongue, and irregular temperature. Within forty-eight hours retention of urine came on, necessitating the use of the catheter several times a day. Five days after operation, the patient's condition remaining unimproved, he was removed to an empty room with wide open windows. Within twenty-four hours the temperature had become normal and it remained so, and the catheter was required only once, a few hours after his removal. The wound healed without trouble and he remained in this room a fortnight, looking, eating, and sleeping well. He was then moved into the general ward, which was certainly in as good a sanitary condition as those of any London hospital. Within twenty-four hours he became restless and grey, his temperature rose, and he again required the catheter regularly. The need for this again ceased immediately on his removal back to the old room with the open windows; and though he went through a slight attack of influenza, which was then rife in the town and hospital, the old symptoms soon vanished and did not recur; but we kept him in the airy room till his discharge.

If, as I believe will be found to be the case, the poison of re-breathed air tends to cause contraction of arterioles and dilatation of venules, it is easy to understand how diminished arterial supply and sluggish venous outflow must hamper metabolism and render tissue change slow and imperfect. This alone seems to me to be a strong reason for giving operation cases all the fresh air obtainable. The greatest care must of course be taken to keep the surface and extremities warm. The common occurrence of faintness (usually ascribed to "the heat") in crowded buildings or even in crowded streets would seem to show the probability that expired air contains a poison having a powerful effect on the cardio-inhibitory function of the vagus.

And what about exhaustion? Why do most men feel so tired after an afternoon's work in a crowded out-patient room. Why is a long journey in a full railway carriage, even with a comfortable seat, so exhausting to many people? Personally an hour or two in a full carriage with the windows shut will give me numbness in my feet and legs and knock me up for the day, while a railway journey in an empty carriage with open windows does not affect me at all. But most people will be willing to admit that any kind of crowd is tiring. And it is to me difficult to resist the impression that an overdose of waste products, whether of one's own or other people's, must generally interfere with the metabolism of nerve tissue. Can constant exposure to re-breathed air (or sewer gas) be one of the causes of the unexplained neuroses and non-specific nerve degenerations? I feel convinced that infants kept in close rooms are peculiarly liable to convulsions, and I believe that many cases of neuralgia are due to this cause. Paralysis agitans strikes me as being another possible example.

Besides all this I am inclined to believe that one of the essential causes of "idiopathic" anæmia will be found among the volatile products of tissue metabolism, and that expired air, and probably sewer gas also, contains something which when inspired either hinders the evolution of the red corpuscle or breaks up its hæmoglobin. Why are the majority of the members of the nursing and resident staffs of the London hospitals anæmic? As a rule they are not ill-fed or greatly over-worked. The hospitals are well lighted and well warmed, foul wounds are things of the past, sanitation is excellent, except in one particular, and it is this—with so many persons under one roof and with the ordinary means of ventilation at present in vogue it is manifestly impossible to get rid of the products of respiration so rapidly and continuously as to prevent their being re-inspired. Why do hospital patients, adults and children alike, improve so rapidly in colour and vitality when able in the summer to lie all day in the garden? What other condition is common to so many pale people of all classes? Take for instance the city clerk, the Lancashire millhand, the overfed footman, the underfed lodging-house drudge, the coffee-house waitress, the wealthy old lady with a terror of "draughts,"—all these and many and many another live almost entirely in re-breathed air. The pallor of the drudge or the waitress is certainly not due to a sedentary occupation. The fact that indoor occupations are far commoner amongst girls than youths is perhaps suggestive, so far as it goes, as partly accounting for the greater frequency of anæmia in the former. What the hæmoglobin-destroying poison may be, should it ever be proved to exist, whether one or more of the innumerable sulphur compounds, I will not attempt to guess. Why some persons seem immune, why some of those affected become deeply and variously pigmented and others slightly or not at all is to me inexplicable.

Women as they grow older are apt to live much indoors. I believe the fat, flabby, paunchy woman, whether purple or pale, with feeble, irritable heart and "inadequate" kidneys, is usually the victim of re-breathed air. I think it will turn out that many feeble hearts and inadequate kidneys, without any definite history of antecedent acute disease, may at least in part own this cause. It seems as if both anabolism and katabolism had been hindered, and inert fat formed and stored, at the expense of active protoplasm. Is it possible that unexplained and fatal "suffocative breast-pang" may be due to a muscarin-like action of this poison on a degenerate heart?

Quite lately I have had as a patient a clerk in the service of a railway company, who works in a very close office immediately under the roof of a large station. He suffers much from flatulence and constipation during the week, but he assures me he has no trouble from either when he visits his parents' home in the country for the week end. A "close" room will infallibly give me abdominal distension

Digitized by Google

and borborygmi within half an hour and I am inclined to think the purity of the air breathed by the dyspeptic quite as important as his regimen or his teeth. It must, I think, sooner or later be recognised that many of the increasing ills which it has been the fashion to charge on the "hurry and brain fag" incidental to a high state of civilisation and a large population are in reality due to the greater contamination of the air we breathe by the waste products of that population, and that toxins excreted by the lungs will in time take high rank among these as both potent and insidious. If this should come to pass the present ideas anent ventilation must be abandoned as utterly futile, and the need will be felt, not of letting a little air in, but of rushing waste products out, a vastly different matter, for which the Tobin's tube and tiny so-called ventilator are hopelessly inadequate. Our methods of ventilation generally must be more approximated to those now approved by the Colleges for the airing of the phthisical patient; and, above all things, we must sleep in a "thorough draught" of pure air. The "surface ventilator" for sewers—that cheap and effective fouler of our street air—must surely also go.

It would seem that any departure from health is more and more to be recognised as due to some definite cause—mostly to some definite poison—which poison (or its producer) has most commonly been introduced from without; in fact, with some very obvious qualification and reservation, a paraphrase of the first law of motion might almost stand as a first law of medicine—viz., the body in health will continue in health unless acted on by some external poison. Whether or no any fresh grain of truth may have been turned up by my ignorant groping, of this I am certain, that the subject of re-breathed air in its relation to disease affords a grand field for skilled and accurate scientific research.

Darlington.

A CASE OF LARGE CYSTIC ABDOMINAL TUMOUR PROBABLY OF THE BROAD LIGAMENT OR OVARY OF UNUSUAL DURATION AND SLOW GROWTH.

BY J. H. DAUBER, M.A., M.B., B.CH. OXON., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO.

I AM not acquainted with any recorded case of ovarian or broad ligament cyst of large size with a history of over fifty years' duration, and as the following case appears to me to be authentic and genuine it may be of some interest to place it on record.

I saw the patient on two separate occasions in my out-patient department at the Hospital for Women, Soho, with an interval of several months between them—the second time being in February, 1897. On both occasions careful notes of her statements were taken and she was subjected to a somewhat severe cross-examination. She was frank, candid, and intelligent, and made no statements of a contradictory and inconsistent character. She gave her age as seventy years, and was a thin, small, and shrunken woman. Her leanness was less noticeable when she was dressed, because of the distension of the abdomen; moreover, she wore a large amount of padding over the chest, as she explained, "to correspond with her stomach." Upon examination the abdomen was seen to be completely occupied by a large tumour extending from the pubes to the ensiform cartilage and bulging on either side as she lay on her back beyond her body. The tumour was not very tense; it was uniformly dull on percussion; the flanks were resonant and the area of dulness was not altered by change of position. Fluctuation was easily obtainable wherever the dulness extended. The girth at the umbilicus was 43 in. *Per vaginam*, senile atrophic changes were well marked. The uterus was small, low, and moveable.

The history she gave was that as a girl as far back as she could remember she was always "high-stomached," but that at fourteen or fifteen years of age this became so noticeable that people commented upon it, so much so, indeed, that her father—her mother being confined to bed at the time—took her with him to consult Mr. Cumplin of Charterhouse-street, who after examining the abdomen called her father aside and informed him that he considered she was pregnant. Her father was doubtful and said: "Well, be that as it may, she shall not leave my roof till it is over." The tumour continued to increase if at all very slowly, and at the end of about ten months her father took her to see Mr. Cumplin again, who then admitted he had been in error and advised the patient to consult Dr. Frederick Bird of Brook-street. Her mother took her to him and the patient was very positive that she was not more than fifteen years of age—certainly not more than sixteen—at the time of this visit. Dr. Bird pronounced the swelling to be due to an ovarian tumour. He seems to have taken much interest in the case and the patient speaks most gratefully of his kindness throughout a long series of years. She invariably declined all operative measures, even tapping, when suggested to her, though from time to time Dr. Bird and Sir Spencer Wells, who saw her with him on more than one occasion, pressed her to undergo operation. For a time she was in Dr. Bird's private hospital in Carey-street, Lincoln's Inn, which, according to the patient's statement, he carried on with five other medical men "each having one bed and paying the cost of it."

The patient was twice married, first in 1843, when she says she was nineteen or twenty years of age—but either age would make her over seventy years old now. Her first husband died when she was six months pregnant with her first child, about two years after marriage. She was married again in 1849, and this time to Dr. Bird's coachman, and so remained under Dr. Bird's observation for many years. She had four children, one—which was posthumous—by her first husband; three by her second. The first child was a boy; it was a "crossbirth" and stillborn. Dr. Jameson of Finsbury-pavement attended her. The second child (a girl) was born in 1850; this was also a "crossbirth" and stillborn. A "gentleman from South Audley-street," whose name she cannot recall, attended her with this child. At the third confinement Dr. Bird and Dr. Merriman of Grosvenor-street were present and they succeeded in delivering her of a live child (a girl) who lived to the age of thirty-two years. Dr. Bird, with his friend Dr. Morgan, again assisted her at the birth of the fourth child (a boy) who survived to his fourth year. All the labours were very difficult.

I think from these detailed statements, which to me bear the impress of veracity, there can be but little doubt that her present large tumour was also of considerable size at the age of fifteen years, that it subsequently complicated all her confinements and that it excited much interest in the minds of Dr. Bird, Sir Spencer Wells and some other gynæcologists at a time when ovariotomy had not become an established operation, but when the treatment by tapping was gradually being abandoned in favour of the radical cure. I may add that the patient declines all operative treatment at the present time as persistently as she has done all her life.

Charles-street, Berkeley-square, W.

A CASE OF LAPARO-NEPHRECTOMY IN AN INFANT SIXTEEN MONTHS OLD.

BY J. A. CAMPBELL KYNOCH, M.B., C.M. EDIN.

THE question of operative treatment in cases of malignant tumours of the kidney in young children is one on which there is still difference of opinion. The operation has not received much favour in this country. Thus Bland Sutton states that nephrectomy in such cases is absolutely unavailing (1) on account of the frequent immediate fatal results and (2) the almost certain early recurrence of the disease in those cases that recover from the operation. He tabulates 21 cases of operation for renal sarcoma in children under six years of age with the following results: 12 died from the operation, and of the 9 that recovered all died from recurrence within one year. The late Mr. Greig Smith held that the operation was only justifiable (1) if the tumour was small; (2) if the general condition of the patient was satisfactory; and (3) if the patient was at least four years of age. Keith states that in young children it is doubtful whether it is ever right to operate. In Germany the operation is much more frequently undertaken, except in those cases in which

Digitized by Google

the disease is obviously far advanced. The results, however, are not very encouraging. Thus, of 150 cases (including all ages) collected by Czerny only five lived more than five years after operation, and of his own 12 successful cases only one patient was alive at the end of that period. Aldibert, finding from a collection of 45 nephrectomies in infants an operative mortality of 48 per cent. and an ultimate one (within a short period) of 75 per cent., considers that this operation should not be undertaken except in the very early stages, and Chevalier concludes that operative treatment in such cases is quite unwarrantable. The most recent complete monograph on the subject of sarcoma of the kidney in children is that of Walker of Baltimore, who has collected from all sources 145 cases, 3 of which came under his own observation. Of these 74 were operated upon with the following results: died from the operation, 27; recovered from the operation but had early recurrence, 28; recovered with incomplete subsequent history, 15; cured, 4. Of those included as "cured" each case was reported on at least three years after operation. Walker finds the average duration of life without operation in such cases to be 8·08 months and that with operation 16·77 months, and concludes that although the percentage of cures is only 5·47 per cent., still, in consideration of the invariably fatal termination, operation is justifiable in all early cases and an exploratory incision in all except the very large tumours and advanced cases. In this country cases are recorded which have been operated on with satisfactory results by Mayo Robson and J. D. Malcolm.

The following case is of interest on account of (1) the early stage at which the condition was recognised and thus making it a favourable case for operative treatment, and (2) the age of the child. The case of the youngest infant successfully operated on is recorded by Schmidt of Munich. His patient was six months old and remained well three years after operation. There are about six cases reported where the operation of nephrectomy was performed with satisfactory results in infants under two years of age. Thus Abbe records a case operated on at the age of fourteen months, the patient remaining well four years afterwards.

In August, 1896, a female infant, fourteen months old, was brought to me on account of diarrhœa of some weeks' duration. This was relieved by ordinary means. The family history was good; the child was very weak and emaciated in appearance. On palpating the abdomen there was found a tumour the size of a lemon in the right lumbar region; it was slightly irregular in outline, fairly moveable, solid in consistence, and apparently not tender to pressure. The ascending colon could be made out in front and to the inner side of the swelling; the liver was separated from its upper margin by a resonant area, the spleen was not enlarged, and the left kidney was not palpable. The external genitals were normal. There was no glandular enlargement made out. The heart and lungs were normal. The urine was of specific gravity 1015, amber and contained no albumin, blood corpuscles, or epithelial cells. There had never been hæmaturia. As I had evidently to do with a renal tumour, and as the case appeared to be a very suitable one for operative treatment, I decided upon an operation if the emaciated condition of the child could be improved. In the course of two months there was not the very rapid increase in the size of the swelling which might have been expected, and as the child's condition was if anything more favourable for operation I decided to carry it out, Dr. Foggie giving chloroform and the nurse assisting me. A vertical incision was made over the tumour slightly inside the anterior superior iliac spine, my intention at first being to remove the tumour extra-peritoneally. This I found would cause delay and difficulty in reaching the pedicle. The peritoneum was opened, the opposite kidney was made out, the incision enlarged, the posterior layer of peritoneum opened, and the tumour with its capsule easily detached. The renal vessels were ligatured together with silk, then the ureter separately, and both were returned into the abdomen. There was very little hæmorrhage and, satisfying myself that oozing had ceased, the wound was completely closed with interrupted silkworm gut sutures and dressed with iodoform and boric powder. The child stood the operation, which lasted twenty minutes, well. On the following day the temperature was 102° F. and the pulse was 140 and on the fifth day the temperature was 103°, when a stitch abscess was discovered. Two sutures were removed, when the temperature came down to 99°. The stitches were all removed on the tenth day and the subsequent history was one of steady recovery.

On examining the kidney the tumour, brain-like in appearance, occupied the greater part of the organ, the kidney itself being represented by a band extending over the front of the tumour and seperated from the latter by a capsule. A piece of the tumour was examined by the Clinical Research Association. The following is the report: "The tumour is clearly of the adenomatous type—that is, tubules embedded in a loose and delicate cellular tissue. In places the stroma contains many round and oval nuclei and here the tubular arrangement of the neoplasm is not distinct; the appearance is that of solid cords of epithelial cells. The present specimen would be called by some an adeno-sarcoma, but there is not sufficient evidence from the piece of tissue examined to pronounce it malignant as it would be desirable to examine further sections and search for striped muscle cells and sarcoma tissues."

The child has now been under observation for nearly two years and appears to be in perfect health as compared with its appearance before the operation. The result, I think, justified the line of treatment adopted, even should recurrence yet take place.

Dundee.

TWO CASES OF

ACUTE DIFFUSE CELLULITIS OF THE SUB-MAXILLARY REGION (ANGINA LUDOVICI) IN WHICH TRACHEOTOMY WAS PERFORMED; RECOVERY IN ONE.

BY H. W. WEBBER, M.S., M.D. LOND.,

ASSISTANT SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

FOR permission to publish the reports of these cases I am indebted as to the first to Mr. W. H. A. Jacobson, senior assistant surgeon to Guy's Hospital, to whom at the time I was acting as house surgeon, and as to the second to Mr. Connell Whipple, senior surgeon to the South Devon and East Cornwall Hospital.

CASE 1.—A woman, aged forty-three years, was admitted to Guy's Hospital at 8·30 P.M. on Feb. 27th, 1892, under the care of Mr. Jacobson, suffering from an inflammatory swelling of the neck with dyspnœa. The history obtained was that three days previously she had fallen against the sharp edge of a chair and had bruised or cut her chin. The wound became inflamed and the redness and swelling increased rapidly up to the time of her admission. The whole of the tissues between the chin and the sternum and between the sterno-mastoid muscles of each side were then in a condition of brawny, inflammatory œdema, and the patient was dyspnœic and of bad colour. She was taken into the ward used for "septic" cases and shortly afterwards, in response to an urgent summons, I found her sitting up in bed moribund from asphyxia. She was at once laid back and an incision was made deeply from chin to sternum in the middle line through the inflamed tissues. These yielded nothing but dark blood and serum and the incision was rapidly deepened until the trachea was found at about 5 in. from the skin surface and slightly to the left of the middle line. It was opened and a sinus-forceps inserted, while the bleeding from the cut surfaces was stopped by the application of pressure forceps (some of which were left *in situ*) and sponges wrung out of boiling water. As no tracheotomy tube was sufficiently long to reach the tracheal opening a Symonds' œsophageal tube was inserted and the cavity round this was powdered with iodoform and tightly packed with strips of sal alembroth gauze, to avert, if possible, the entrance of septic material into the trachea. A hot boric fomentation was placed round the neck over all and changed every two hours. The patient was ordered to take 1 oz. of the mistura spiritus vini gallici every four hours and she was directed to breathe near a steam kettle. On the 28th she was better. Her pulse was 130. The sal alembroth strips were changed and the Spencer Wells's forceps were removed. The next day her temperature was 102° F. and the respirations were 20. The A. C. E. mixture was given, and about a dozen free incisions were

Digitized by Google

made into the still much inflamed neck. These openings were dilated with a steel director and dressing-forceps, and drainage-tubes were placed in two of them. Hot boric fomentations were continued as before and the trachea and the large wound were treated in the same manner. On March 1st her temperature was 101·4°, and the swelling of the neck had subsided considerably the discharge from all the wounds was now purulent in character and quite sweet smelling. The Symonds' tube was removed from the trachea and the whole wound was packed with gauze strips in a square of butter-muslin. Respiration was easy and quiet. She was now ordered a mixture containing 2 grains of quinine every four hours and a pint of champagne and 4 oz. of brandy in the twenty-four hours. The hot boric fomentations were continued. On the 2nd the patient's temperature was 98·4° and the discharge from the wound was sweet. The sal alembroth strips were changed three times in the twenty-four hours. The neck was much smaller in size and the tissues were soft. The tracheotomy wound was beginning to close and there were no adventitious respiratory sounds. The after history of the case was uneventful and she left the hospital early in April.

CASE 2.—A woman, aged twenty years, was seen with Dr. Hay of Plymouth on May 29th, 1898. The history was that three days previously she had consulted Dr. Hay for a swelling in the right submaxillary region. This corresponded to a carious tooth and Dr. Hay advised its removal by a dentist. The patient was not seen again until the morning of the 29th, when her neck had become much swollen on the right side, the swelling extending to the middle line, and her general condition was much worse. The tooth had not been removed. Dr. Hay made a median incision below the chin and ordered the application of hot linseed poultices and prescribed a mixture containing tincture of perchloride of iron every four hours. In the evening, as her condition was becoming serious, I saw her with Dr. Hay about 10 P.M. She was then sitting up in bed. She was of a dusky purplish colour, her pulse was 120, and her temperature was 102° F. There was a brawny inflammatory swelling extending from the lobule of the right ear to the hyoid bone and upwards to the chin and lower jaw. The floor of the mouth was involved and the tongue was of a purplish colour and pushed up against the roof of the mouth. There was much dyspnœa and speech was impossible. Chloroform was cautiously given and I first deepened the incision below the chin opening up the subfascial tissues after Hilton's method. Another curved incision was then made in the right submaxillary region and the deep parts were opened up in a similar manner. From both the wounds dark blood and a little dark-coloured pus exuded. An attempt was then made to extract the carious tooth but it caused such dyspnœa that it was abandoned. The hot poultices were reapplied. On the 30th the patient was somewhat better. The pulse was 110 and the temperature was 101°. The swelling had gone down a little and she could swallow liquids. On the 31st she had a change for the worse. She was more cyanosed and dyspnœic and the left submaxillary region was swelling. As her surroundings were of a poor description and nursing was practically *nil* I advised her removal to the South Devon and East Cornwall Hospital. This was delayed until the following morning, June 1st, when she was admitted at 11 A.M., I saw her at midday and unexpectedly found her better. Her tongue was of a red colour and she was able to protrude it from the mouth. She could articulate and could swallow beef-tea fairly easily. The incisions on the right side were beginning to granulate but there was still much swelling on both sides of the neck. It was decided not to interfere further for the present and hot boric fomentations were ordered to be applied every hour. About 7 P.M. she became suddenly attacked with dyspnœa. A little chloroform was given and I incised the left side of the neck, only dark blood flowing from the wound. Directly this was done respiration ceased. A long incision was immediately made in the middle line and was rapidly deepened, but the trachea could not be found, and after a search with the finger it was felt on the left side of the neck at the depth of the forefinger from the skin and some 2 in. from the middle line. The knife was pushed along the finger and the trachea was opened and kept open with sinus forceps, and artificial respiration was performed, but the patient failed to recover.

The symptoms in the latter case were somewhat fluctuating, but I regret that I did not perform tracheotomy earlier, before the trachea, pushed across by the swelling on the right side, had become compressed by that on the left.

Plymouth.

THREE CASES OF PLAGUE IN PREGNANT WOMEN; RECOVERY IN ALL THREE CASES.

BY B. H. F. LEUMANN, M.B. LOND., D.P.H. CANTAB.,
CAPTAIN I.M.S.; MEDICAL OFFICER IN CHARGE OF PLAGUE WARDS, ST. GEORGE'S HOSPITAL, BOMBAY.

As it has been stated by competent observers that during the epidemic of plague in Hong-Kong "every pregnant woman aborted and every woman who aborted died," it may be interesting to record the three following cases which have lately been under my care in the Plague Wards at St. George's Hospital, Bombay. Of these three women two came into hospital in a pregnant condition and one aborted at the beginning of the tenth day of her illness, while the other left the hospital without any abortion having occurred. The third case aborted before admission into hospital and soon after admission was considered by Dr. Yersin to be too far advanced to be injected with his serum.

CASE 1.—The patient was a woman, aged twenty years, a young Eurasian. She had been married eight months, had had no children and no miscarriages. She was admitted to hospital at 4 P.M. on Feb. 9th, 1898, after nearly twenty-four hours' illness. With regard to her history she awoke feeling quite well on the 8th, but soon after rising suffered from severe frontal headache and malaise. At 5 P.M. she had a rigor which lasted ten minutes and was followed by cramps in the hands and feet. At 6 P.M. she vomited profusely and first noticed a "painful lump in the left groin." The vomiting and fever continued unabated all night and till admission. During December and January she had had morning sickness, but it had ceased on Jan. 28th. There had been many cases of plague in her neighbourhood. On admission she was found to be a well-nourished young woman, with a flushed face, dilated pupils, injected conjunctivæ, and anxious though dull expression of countenance. The skin was hot and dry, the temperature was 105° F., the pulse was 130, soft and regular, and the respirations were 40, but quite regular. The tongue was covered in the centre with a silvery-white fur, slightly moist; the edges and tip were bright red. She lay on her back with both legs drawn slightly up and the left foot crossed over the right; her hands were extended above her head. She had scratches on both her feet. She complained of great frontal headache and cough. On examination all the abdominal and thoracic organs appeared to be healthy. Towards the inner part of the left femoral region was a mass of the size of a walnut surrounded by slight œdema and extremely painful on manipulation. The skin over it was not reddened and the swelling was quite distinct from the inguinal glands, which could easily be felt but were not painful. No other glandular enlargement was detected. The urine was very acid, of specific gravity 1018, no albumin and no sugar. On the 10th she had slept fairly well but could not retain her food. The bubo had increased in size and was more painful. The temperature had fallen to 101·2°, the pulse was 136, and the respirations were 32. She was extremely drowsy and resented being roused. In the evening her temperature reached 105·2° and the vomiting was more constant. On the 11th the vomiting was not relieved at all. The cough was much less. The bowels were opened after administration of calomel; large scybalous fæces were passed. She was very drowsy now as she had hardly slept all night. There was extension of the œdema to the left inguinal glands and the bubo was much more painful. No other glandular enlargement could be felt. The temperature in the morning was 103·8° and in the evening was 102·8°. Her condition continued much the same until the evening of the 12th, when she became delirious—low muttering—and continued so all night. The temperature on Feb. 12th in the morning was 103·8° and in the evening was 104·2°. On the 13th she was extremely weak and drowsy but not unconscious. When awake she was extremely nervous and difficult to manage. She vomited frequently, mostly after partaking of milk. The bowels were constipated. The physical signs were as before. The temperature in the morning was 100·2° and in the

Digitized by Google

evening was 105·2°. On the 15th the patient—who had been delirious for two nights but the previous night was violently so, constantly trying to get out of bed—was now quiet. She complained of cough and burning pain in the chest. On examination moist râles were audible on both sides, back and front. The abdominal organs were apparently normal. The bowels were opened daily after small and frequent doses of calomel; they were semi-solid and very offensive and yellow in colour. The pulse was 140 and dicrotic. The temperature in the morning was 103·0° and in the evening was 102·6°. Pain and distension of the abdomen began in the afternoon, but had been relieved by turpentine enema and stupes. On the 16th there was no pain in the chest. The cough was almost absent; there was no headache; she was quite conscious but extremely weak. The temperature in the morning was 102·0° and in the evening 101·8°. On the 17th the patient—who had slept well during the previous night—was much exhausted after vomiting her meal of broth at 8 P.M. The signs were the same as before, but the bubo was less œdematous and more painful. There was slight abdominal distension and pain. Towards evening the pains in the abdomen had increased and at 8 P.M. they were extremely severe. At 3 A.M. sudden bearing-down pains occurred and she aborted at 5 A.M. (fœtus of three and a half to four months). The placenta was slightly adherent and was removed by the finger. There was slight hæmorrhage afterwards. The temperature at 8 A.M. had fallen to 99 4° and the patient seemed quite comfortable and much relieved; she was sleeping soundly. The evening temperature was 102·0°. On the 18th the vaginal discharge was free, sweet, and alkaline, and yellow in colour. (Perchloride of mercury, 1 in 2000, was used as a vaginal douche night and morning.) The patient was comfortable though her temperature had risen. The temperature in the morning was 100·8° and in the evening was 102·4°. On the 19th she had slept well. The discharge was yellowish red, thick, and slightly offensive. The right eye was affected with iritis. There was no pain elsewhere except in the bubo. The temperature in the morning was 101·8°, and in the evening was 103·2°. On the 20th the vaginal douche was used thrice daily as shreds of membrane and placenta were coming away. The pain in the bubo was very great. The patient had severe headache all day. The temperature in the morning was 101·6° and in the evening was 102·6°. On the 22nd the temperature had reached normal and kept fairly low. The vaginal discharge was sweet and scanty, yellowish, and thin. There was much pain in the right eye and the pupil was irregular, with surrounding chemosis of the conjunctiva. The tension of the right eye very much increased. The temperature in the morning was 99·2° and in the evening was 99·2°. On the 23rd a drop of pus was let out of the right eye and afforded instant relief. The bubo showed signs of commencing suppuration. The temperature in the morning was 98·4° and in the evening was 98·8°. On the 25th the bubo opened and about 1 oz. of creamy pus escaped. The general condition was much improved. From this date the patient continued to rally in strength; on the 25th vaginal discharge entirely ceased and though the bubo was long in healing she wa soon able to sit up in bed and take solid food. The temperature remained low and hectic in character for about two weeks and then fell to normal. The patient was discharged from the plague wards on March 12th, only slight iritis remaining to worry her.

Bacteriological examination.—On Feb. 10th bacilli resembling those of plague were found by puncture of the bubo and microscopical examination of the lymph exudation which escaped. A culture was made on slanting agar-agar and showed numerous colonies of plague bacilli (examined and proved both microscopically and by experiments on mice) the next and second day. On the 15th the blood was examined both microscopically and by stroke cultivations on agar-agar. No colonies of any sort were found.

Treatment consisted mainly in stimulating liquid diet and good nursing. Milk, as much as she could take, with strong beef-tea, egg-flip, &c., formed her staple food. Thirst was relieved by ice to suck. Medicinally from the first she was put on a mixture containing 3 minims of carbolic acid, 5 minims of tincture of iodine, 2 drachms of mucilage of gum acacia with water to 1½ oz. This was given every three hours for the first day and after that four times daily till Feb. 14th. A boric acid fomentation was kept continually on the bubo and helped greatly to relieve the pain. Whenever the temperature rose to 104° she was sponged down with weak vinegar and water and the wet pack was resorted to when it reached 105°. As cardiac stimulants brandy and strychnine were freely given. Digitalis proved very useful in slowing and regulating the pulse-rate. Other treatment for cough, vomiting, constipation, &c., was purely symptomatic. To produce sleep and quiet delirium morphia and atropine given hypodermically proved far more effective than hyoscine, bromidia (which is far too depressant for these cases), or other drugs. Tonics and oleum morrhuæ were given during convalescence.

CASE 2.—The patient was a woman, aged thirty-four years, who first came under my care and then under that of Surgeon-Colonel J. Arnott, physician in charge of St. George's Hospital, Bombay, by whose permission I publish the notes of her case. On Feb. 11th, immediately after breakfast at 10 A.M., she felt giddy and sick and took to her bed and while undressing noticed her left femoral glands to be swollen. In the afternoon fever supervened and these symptoms continuing all night she was sent to hospital and was admitted at noon on the 12th. She had no rigor or vomiting. Menstruation had not occurred for nearly three months and she considered herself pregnant. On admission she appeared to be dull, lying in a crouching attitude with her legs drawn up and her head forwards on to her chest. The skin was hot and dry; the temperature was 104·4° F.; the pulse was 120, soft and feeble. The tongue was furred, white in the centre, with the tip and edges irritably red (typical). The thoracic and abdominal organs were apparently healthy. In the left femoral region two glands were found enlarged to the size of a hazel-nut each and they were very tender. There was no other glandular enlargement. On the 13th the patient had slept badly and now had great frontal headache. The glands in the left femoral region remained the same. The specific gravity of the urine was 1022; it was very acid; there was no albumin and no sugar. The temperature in the morning was 102·4° and in the evening was 102·0°. On the 14th the patient's headache prevented her sleeping, though she was distinctly dull and drowsy. The urine was neutral and contained phosphates in large quantity. The temperature in the morning was 101·6° and in the evening was 102·0°. On the 16th the patient was very weak. Her face had an "earthy" hue and she looked extremely dull and drowsy. The buboes were more painful and swollen. The physical signs were the same as before. The temperature in the morning was 100·2° and in the evening was 102·6°. On the 17th the temperature had reached normal and the patient said she felt much better, but her appearance and signs remained unaltered. From this date she made an uninterrupted recovery, the glands undergoing complete resolution, and she left the hospital well in a fortnight.

Treatment was practically the same for this case as for the former one, except that for the first twenty-four hours she was given the carbolic acid and iodine treatment mentioned above; but after that, when under Surgeon-Colonel Arnott's care, 15 minims of solution of chlorine in water every six hours was substituted and seemed to agree very well. Other treatment was mainly symptomatic.

No microscopical or bacteriological examination was conducted in this case, but from the clinical symptoms and the fact that she had attended on one of her servants who had suffered and died from this disease there seems to be absolutely no doubt that she suffered from a mild attack of plague in its bubonic form.

CASE 3.—The patient was a married woman, aged thirty-one years, a Eurasian, living in a very infected district. She had had two children born at full time and no miscarriages. She was admitted at 6 P.M. on March 11th after three days' illness. With regard to her history, on the evening of March 8th she had felt pain in the right groin and had detected a small swelling there. The next day she did her household work, but at 4 P.M. suddenly had a severe rigor, which lasted nearly one hour and was followed by frequent vomiting, frontal headache and fever. At 3 P.M. on the 10th severe abdominal and bearing-down pains set in and she aborted at about 5 P.M. (fœtus three and a half months). A Hindoo medical attendant removed the after-birth, but apparently failed to diagnose the case though aware of the existence of the painful glands above mentioned. On admission the patient was found to be a thickly-set woman, with flushed face, dull expression, dilated pupils and congested conjunctivæ. She lay on her right side with both

Digitized by Google

legs well drawn up to the abdomen. The temperature was 104·6° F., the skin was hot and dry, the tongue was coated with a silvery white fur in the centre, the tip and edges were red and cracked; the breath was foul; the respirations were 28 and shallow; and the pulse was 124, but of fair volume. The thoracic and abdominal organs were apparently natural. The right femoral and inguinal glands were much enlarged, though distinct from one another, and they were surrounded by considerable brawny œdema. The whole tumour measured 3½ in. by 4½ in. and was extremely tender. The skin overlying it was slightly reddened and not moveable on the surface of the swelling, but no fluctuation could be detected. The lochia were very free, light yellow and sweet. The external os admitted the little finger; the internal os was dilated to admit the finger, by which means several small bits of placenta and shreds of membrane were removed. The cavity was washed out with a 1 in 3000 perchloride of mercury solution and similar vaginal douches were ordered twice daily. On the 12th, the morning after admission, the patient was seen by Dr. Yersin, who refused to inject her as he considered her case to be hopeless. The temperature had remained high, but the lochia were sweet and the pain in the bubo was slightly less. The urine was dirty yellow, of specific gravity 1020, slightly albuminous, and neutral. On the 13th, though much improved in the morning, she became very restless towards night and at 11 P.M. complained of severe pain in both iliac regions. On examination no swelling was detected. The temperature in the morning was 102·0° and in the evening was 104·8°. On the 14th there was no more pain in the abdomen, she looked much better, and the bubo was considerably enlarged in size. The temperature in the morning was 103 0° and in the evening was 102·4°. On the 15th, the temperature remaining high, she was given 10 gr. of antefebrin in brandy at night. This greatly relieved the headache as well as being effectual in reducing the temperature 3° F. On the 17th the bubo was opened. Caseous pus and blood escaped. Beyond copious sweating she complained of nothing. There was no pain and no other swellings were detected. The temperature in the morning was 99·6° and in the evening was 101·0°. From this time the patient progressed quite favourably. On the 22nd the incision in the bubo was considerably enlarged and two more suppurating sacs were opened. On April 1st she was discharged well.

Bacteriological examinations of her blood were made on March 12th and 16th, but the agar tubes remained perfectly sterile. On March 17th cultures on slanting agar were made from the caseous pus and yielded many colonies of plague bacilli and a few streptococci, which were examined microscopically.

The treatment in this case was practically the same as in Case 1 and needs no further comment.

I have to thank Dr. Bitter of Cairo and Professor Gaffky for their kindness in allowing me to work in their laboratory and for confirming the bacteriological and microscopic investigations of the above cases. I am also indebted to Assistant Surgeons Lafonde, Netscher, and Macgregor of St. George's Hospital, Bombay, for their help in observing these cases clinically.

Bombay.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on Sept. 8th, 1898, Mr. Wm. Berry, F.R.C.S.I., President, being in the chair.—Dr. Blair read a paper on the Serum Treatment of Puerperal Septicæmia, which he illustrated with copious notes from a successful case in his own practice. The usual methods of treatment were also adopted throughout. Anti-streptococcic serum was used. The serum was best employed early in the disease and then towards evening, and in all cases collapse must be watched for and obviated. The belief was expressed that recovery from puerperal septicæmia treated with serum would be more thorough than with other methods alone.—Dr. Blair said it was desirable that the serum should be of standard strength and purity so that definite results could be obtained.—In the discussion on the paper the following gentlemen took part: The President, Mr. Parker, Mr. Jones, Mr. Graham, Mr. Monks, Mr. France, and Dr. Rees and Dr. Benson.—Dr. Blair replied.—A vote of thanks to Dr. Blair for his paper was moved by Dr. Benson, seconded by Mr. Monks, and carried unanimously.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE OCCURRENCE OF CARTILAGINOUS AND BONY NODULES OF THE TONSILS.

BY WYATT WINGRAVE, M.R.C.S.ENG.,
ASSISTANT SURGEON AND PATHOLOGIST TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

IN an article published in THE LANCET of August 13th last Dr. Hugh Walsham drew attention to the existence of cartilage and bone in the faucial tonsil and expressed the opinion that they were vestigial in origin, whilst Dr. Kanthack believed that they were due to some metaplastic process. I am quite of the view that these cartilaginous masses originate in developmental vestiges and have always considered them to be identical with the subpharyngeal cartilage of Luschka, referred to in Macalister's "Anatomy,"[1] but with regard to the bony masses in some instances I am inclined to agree with Dr. Kanthack, since they are generally multiple, being often scattered about the substance of the tonsil and they are often associated with morbid changes in that structure. Still, Dr. Walsham's example of transition proves a possible chondral origin.

My experience is that cartilaginous nodules are by no means rare in this situation. Several years ago I exhibited sections at the British Laryngological and Rhinological Association and in January last further examples at the Laryngological Society of London.[2] These nodules were found accidentally during the microscopical examination of diseased tonsils—mostly chronic hypertrophy—removed from patients below twenty years of age. Dr. Walsham's were, however, associated in two instances with the more mature ages of twenty-seven and fifty years, Deichert's case being as old as seventy-seven years. As in those cases, the cartilage was hyaline and white fibrous, embedded in a dense connective tissue capsule, sometimes occurring in the fibrous "bed" and sometimes in the lymphoid pulp of the tonsil, but never in the lymph nodules or follicles. I have only found calcification in one instance and this was not truly osseous. It is interesting to note that in Dr. Walsham's cases the tonsils were atrophied and that the bony elements were in excess of the cartilaginous. There must be considerable difficulty in forming a true estimate as to the frequency in the occurrence of these "nodules," since they are generally found by accident; still I have no doubt but that a systematic search will prove them to be much commoner than is generally believed. It is not an unusual experience when operating to find considerable resistance to the guillotine quite disproportionate to the density of the tonsil tissue. This I have in several instances proved, by the aid of a pocket lens and the fingers, to be due to the presence of fibrous and cartilaginous tissue, which was confirmed by the microscope. The fact that all my cases were young subjects is, perhaps, sufficient explanation for their being solely cartilaginous, since in the second instance described by Dr. Walsham there was partial ossification. That these nodules may as "vestigial rests" be the possible and probable foci of neoplastic changes must not be ignored, and as they are of somewhat more than transcendental interest further research as to their frequency and association may prove valuable.

CASE OF LARGE FATTY TUMOUR.

BY J. A. HAMILTON, M.B., C.M. EDIN.,
LIEUTENANT, I.M.S.

AS cases of very large tumours are comparatively rare nowadays the following may be of interest. I am away from books of reference at present, but I do not think that

[1] A Text-book of Human Anatomy, by Alexander Macalister, 1889, p. 596.
[2] Proceedings of the Laryngological Society of London, vol. v., p. 34.

Digitized by Google

fatty tumours often reach such a size as the one described below.

The patient, a Manipuri, came to me in March, 1897, when I was officiating as civil surgeon in Manipur. He said he was forty years of age, but he looked more, and was very thin and feeble. He stated that the tumour had been present for about fourteen years, that it had first appeared on the back of his shoulder in the supra-spinous region, and that it had gradually attained its present position as it increased in size. It now hung from the right side of the thorax, the line of attachment crossing the posterior axillary line obliquely downwards and forwards. Looking at the patient from behind he gave the appearance of a *bhisti* carrying a *mussuk*. He stated that the tumour had not perceptibly increased in size during the last three years. He had tried all sorts of native medicines and applications, and finally, as he found it in every sense of the term a burden to him, he came to the Civil Dispensary to see if anything could be done for his relief. The nature of the tumour was made out without any difficulty and its removal recommended; to this he gladly consented. Accordingly a few days later I amputated it; I made an eliptical incision, turned the flaps back, and easily separated the tumour from its surroundings, removing it with most of its skin covering. The only difficulty lay in the number of very large superficial veins which had to be secured and in the size of the tumour, which made it very unwieldy and awkward to handle. I unfortunately made the flaps a trifle small, so, owing to tension, I had to cut two stitches next day, but even with this the wound completely healed within three weeks. The tumour was carefully weighed half an hour after removal and it turned the scale at just over 37½ lb. I saw the patient two months later. He was very fit and had put on weight, he could get about easily and had even been playing polo, a thing he had not been able to do for years.

Gantok, Sikkim.

[The above article was accompanied by photographs of the patient taken before removal of the tumour. It had the appearance of an enormous pyriform mass larger in circumference than the man's waist, projecting backwards and sideways so much that it could be seen in whatever position he stood with reference to the observer.—ED. L.]

IPECACUANHA IN A CASE OF EPILEPSY.

BY C. KNOX BOND, L.R.C.P. LOND., M.R.C.S. ENG.

THE treatment of epilepsy remains so unsatisfactory that any suggestion derived from the treatment of individual cases of this malady may possess some therapeutic value.

The following note refers to an unmarried woman, aged twenty-nine years, a patient at the St. George's and St. James's General Dispensary, who had been subject to epileptic fits from the age of eight years. When the fits first commenced they were described as "faints," but from the onset of the catamenia they assumed a more serious form, when she was taken to a special hospital for nerve diseases for a period of six months and was said to have received no benefit from treatment. She was then treated at a general hospital continuously for two years and since then has been more or less under treatment at the hands of several physicians. On July 14th, 1897, she was admitted to the above institution under the care of Dr. Alfred Eddowes, who found that she had taken continuously for a long period large doses of bromide without, according to the statement of her mother, diminishing the number or severity of the fits. Dr. Eddowes therefore decided to reduce the bromide to a third of the former dose and added vinum ipecacuanhæ to the prescription. A dose of 10 minims was commenced with, increased from time to time as the fits recurred until a dose of 40 minims three times a day was reached. With each increase of ipecacuanha there was a marked improvement in the patient's condition. The severity and frequency of the fits had diminished under this treatment until May 3rd, 1898, since when no fits have occurred. The patient's mother stated that her daughter had never enjoyed so long an immunity from fits at any previous period since their commencement.

The reasons which led Dr. Eddowes to adopt this treatment were based, firstly, on his observation in his former private practice as to the value of ipecacuanha in convulsive attacks of children apparently due to gastro-intestinal irritation; and secondly, that it seemed a likely remedy to check the voracious appetite and neglect of mastication so frequently observed in epileptics. The marked improvement with this treatment so noticeable in a very intractable case under my observation for nearly three years leads me with Dr. Eddowes's concurrence to submit this brief note for publication in THE LANCET.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GREAT NORTHERN CENTRAL HOSPITAL.

A CASE OF GASTRO-JEJUNOSTOMY IN WHICH THE ARTIFICIAL OPENING WAS SURROUNDED WITH A TRIPLE ROW OF SUTURES AND LINED WITH MUCOUS MEMBRANE.

(Under the care of Mr. C. B. LOCKWOOD.)

THE best method of uniting two portions of the alimentary canal has been much discussed in recent years. There are at present two chief parties; first, those who advocate the employment of only a needle and suture, and those who call in the aid of various mechanical appliances. By a needle and suture it is quite possible to unite two pieces of intestine completely and successfully, but even the most ardent supporters of this method must acknowledge that in some cases at least the process is lengthy. The advocates of the employment of "apparatus" in enterectomy or gastro-enterostomy claim that the duration of the operation is materially shortened. It is true that some little time is saved in the operation, but the presence of the "apparatus" is in itself a danger. In some cases it may be important to terminate the operation at the earliest possible moment; in these a Murphy's button or other "apparatus" may be usefully employed, but if it be possible safely to prolong the operation a simple suture will offer less chance of troublesome complications. The method of suture employed by Mr. Lockwood in the following case is ingenious, and a very thorough joint results; the only possible objection which can be raised is that the operation requires no small amount of time; but practice in the method would go far to obviate this objection. Gastro-jejunostomy is a valuable, though of course only a temporary, method of treatment of cases of malignant disease of the pylorus, in which no attempt at removal can be made. It is also of permanent value in cases of non-malignant pyloric obstruction, but for this condition a Heineke-Michulicz operation is usually preferable.

The patient, a man, aged fifty-four years, said that he had had syphilis in his youth, but otherwise his history was good. He had not been a hard drinker. In October, 1895, he began to have dyspepsia and pain after food. In November he vomited occasionally after food; soon he began to vomit all solid food; and when he was admitted to the Great Northern Central Hospital on Jan. 1st, 1896, he had commenced to vomit liquids. No blood was seen either in the vomit or in the motions. A rapid loss of weight accompanied this illness, so that he had become exceedingly emaciated and so weak that he had to be carried into the ward. A hard ovoid swelling, the long diameter of which was about 3 in. and the short diameter 2½ in., was easily felt through the thin abdominal walls beneath the eighth right costal cartilage and in the situation of the pylorus. The stomach was dilated and reached before the level of the umbilicus. A succussion splash could be heard and felt. The tumour of the pylorus was rather tender and moved freely with the descent of the diaphragm. It was soon ascertained that all the fluids which the patient swallowed were vomited mixed with gastric juice

Digitized by Google

and having a very sour and unpleasant smell. He was made more comfortable by washing out the stomach, but in spite of rectal feeding he said that he felt starved. Dr. Clifford Beale, under whose care the patient had been admitted, requested Mr. Lockwood to see him with a view to an operation being performed. As he was eager to obtain relief from his horrible sufferings endeavours were made forthwith to diminish the size of his stomach and to improve its condition by daily washing it out with boric lotion. Mr. H. Randall Wadd carried this out with great assiduity and without a doubt much is due to his efforts. After the patient had been under observation for a fortnight and with little alteration in his condition Mr. Lockwood performed the following operation. A vertical incision about 5 in. long was made through the centre of the left rectus abdominis muscle so as to expose the front of the stomach. This incision began about an inch below the left costal margin. It was at once ascertained that at least 5 in. of stomach and jejunum would have to be resected to take away the disease; also an enlarged lymphatic gland was felt in the gastro-hepatic omentum. As there was no prospect of the patient bearing such a formidable operation the commencement of the jejunum and the front wall of the stomach were drawn out of the wound and the great omentum was pushed back with a flat sponge. The stomach and jejunum being now held together were sewn to one another for three inches by a row of interrupted silk sutures. All of these were cut short except the two end ones. These being left long were a useful landmark and helped to steady the stomach and bowel. This first row of sutures only transfixed and fastened together the peritoneum. It was parallel to the great curve of the stomach and to the mesenteric edge of the jejunum and about half an inch from both. The peritoneal row of sutures having been inserted an incision at least one and a half inches long was made through the peritoneal and muscular coats of the stomach and jejunum. This cut was the beginning of the artificial opening and was a third of an inch from the peritoneal row of sutures and opposite its middle part. It brought the mucous membranes of the stomach and of the jejunum into view. These mucous membranes were easily separated from the muscular coats of the stomach and jejunum for about a third of an inch all round the incision.[1] When this had been done the peritoneal and muscular coats of the stomach and of the jejunum were sewn together with a row of interrupted sutures parallel to the row in the peritoneum. When the second row of sutures had been cut short the stomach and jejunum were both opened by cutting through their mucous membranes. These were sewn together by a row of interrupted sutures parallel to the last two rows. By this stage of the operation openings had been made into the stomach and jejunum and the edges of the opening next to the great curve of the stomach and next to the mesenteric border of the intestine had been sewn together by three parallel rows of sutures—the first through the peritoneal cone, the second through the peritoneal and muscular coats, and the third through the mucous coat. At this stage two of these rows of sutures (the first and the second) were hidden from view, but the last was still in sight, having been tied on the inner mucous surface of the stomach and jejunum.

Although rather difficult to describe the operation is quite simple up to this point and quite easy to perform. Briefly, an opening has been made into the stomach and into the jejunum, and one side (the lower) of the opening has been fastened together with three rows of interrupted sutures. To complete the operation it is only necessary to sew together the other side (the upper) of the opening. This is easily done by sewing together (1) the mucous membrane, (2) the muscular and peritoneal layer, and (3) the peritoneal. In sewing together the mucous membrane nearly all the sutures can be tied on the mucous surface with the exception of the last. The suture of the muscular and peritoneal coat and of the peritoneal coat alone presents no difficulties whatever. The result is an opening from the great curve of the stomach into the jejunum. This opening is lined with mucous membrane and is big enough to admit easily the end of the thumb. The three rows of sutures effectually prevent leakage and are strong enough to guard against the muscular contractions of the stomach and jejunum.

[1] The above method of opening the stomach and jejunum has, Mr. Lockwood finds, been used by Mr. F. Barker and subsequently by Mr. Jessett, Brit. Med. Jour., June 2nd, 1888, p. 1115.

The final stages of this operation were the return of the stomach and jejunum and the closure of the abdominal wound. The whole proceeding took about a little more than an hour, but it was the first time that it had been done and neither the operator nor the assistant were experienced in it. Subsequently the same operation was performed in forty-five minutes upon a patient under the care of Dr. Galloway. It is not quite safe to put continuous sutures into distensile organs, but, nevertheless, in the next case Mr. Lockwood will endeavour to save time by using short lengths of continuous suture.

The after progress of the case was as follows. The shock was very slight, great care having been taken to keep the patient warm during the operation and to ply him with nutrient enemata containing brandy. The next day feeding by the mouth was begun with peptonised meat essence and peptonised milk and milk-and-soda-water. The second day after the operation the patient twice vomited some fluid mixed with bile and gastric juice. The vomiting ceased as soon as his stomach was washed out. His nourishment was gradually increased until the tenth day, when an untoward accident, fortunately attended with no ill result whatever, occurred. With Mr. Lockwood's consent the abdominal sutures were taken out. That evening the patient coughed and strained and a piece of bowel was protruded from the wound. This was replaced and the wound was brought together and healed without any suppuration. It is clear that allowance ought to have been made for the slowness with which wounds heal in such emaciated patients. Moreover, there was no reason why the sutures should not have been left in for another week or ten days. Ten days after the operation the patient took pounded meat and fish without any vomiting and each day he made steady progress. It was found advisable, however, to wash out the dilated stomach occasionally and on Feb. 2nd he walked home. He could then eat an ordinary diet without vomiting. It seemed to be a great pleasure to him to drink beer again. He attended from time to time during 1896 and in October he vomited occasionally. This was attributed to his diet, which consisted of beer, cheese, herrings, and so forth; but in spite of all he had gained 4 lb. in three months. When admitted into the hospital and fed on a light nourishing diet he ceased to vomit and soon improved and was able to help with the ward work. His stomach also required to be washed out, but no dilatation could be discerned. The patient was shown at the Medical Society of London on Nov. 9th, 1896. On Jan. 4th, 1897, he still maintained his ground and so far as could be discovered the pyloric growth had made hardly any progress. He looked well and said he had continued to gain weight.

Remarks by MR. LOCKWOOD.—The above case illustrates a method of sewing together the intestine and stomach in gastro-jejunostomy. I used it twice during the year 1896. Although at first a little more time may be required for its application, nevertheless it seems to promise to be more secure than other methods and to have the advantage of lining the artificial opening with mucous membrane. In the operations by sewing or by using decalcified bone plates, the cut surfaces of the mucosa and serosa of the stomach are left exposed to the corrosive action of the gastric juice. This has always seemed to me to be a great risk, and has probably been the cause of some of the fatal results. But it has to be allowed that apart from this danger the operation of gastro-enterostomy is as yet likely to have a considerable mortality. At present surgeons are called upon to operate when the patients are emaciated to the last degree, worn out with perpetual vomiting, and in the very worst state for an operation which makes demands upon their powers of repair. But it is hard to refuse to make an attempt when there is the faintest chance of relieving, if only for a time, such horrible sufferings.

As yet the operation of gastro-jejunostomy is comparatively rare. In 1892 Mr. Jessett[2] collected 17 cases and in 1894 Mr. Bidwell[3] added 15 more, all done in this country. No doubt when the striking benefit of gastro-jejunostomy is properly recognised it will be done oftener and earlier. From what I have seen of three cases under my own care and of several operated upon by other surgeons the method of operating may be improved upon. Although the delay had been slight yet it is probable that my patients would have been more comfortable after the operation if the stomach

[2] Transactions of the Clinical Society of London, vol. xxv.
[3] Ibid., vol. xxvii.

Digitized by Google

had not been so dilated. Mr. Richard Bevan[4] has very convincingly urged that the operation should be performed as soon as the dilatation is diagnosed. In the two cases, which he evidently watched with much solicitude, great discomfort arose both before and after the operation owing to that condition. But he adds that "the benefits, in spite of discomfort, were enormous."

At present it is the custom with many surgeons to unite the stomach and jejunum with a mechanical contrivance such as a Senn's plate or Murphy's button. The last-named is probably the most popular. It is easier to use than the decalcified bone plate and does not take quite so long to apply Senn's plates have been used less often since cases have been recorded by Stansfield, Larkin, and others of closure of the artificial opening. Cases reported by Keen[5] and Morton[6] show that the button may not be quite free from this danger, but the risk seems to be small. But apart from this the metallic button has to traverse the whole length of the small and large intestine and this journey is often delayed or not completed. In some cases the intestine has sloughed beyond the button[7] and twice for reasons which are not given. Dr. Wiggin[8] mentions a case in which the button stuck in the small intestine and had to be removed by laparotomy, also one in which the weight of the button bent a loop of intestine until it became obstructed, and one in which the button was plugged with hard fæcal matter. The actual success after the use of buttons and mechanical contrivances is not easy to ascertain. Dr. Murphy[9] includes as recoveries patients who died "eleven days later from complication," "four weeks later from diarrhœa," "died fourteen days after, pneumonia," and so on, because the union was good. If the cases of suture were taken in the same way a high proportion of recoveries would be obtained. Indeed, according to the late Mr. Greig Smith[10] Hahn has had fifteen gastro-enterostomies, and Doyen eighteen without a death, neither operator having used any apparatus. Union by suture ought to appeal very strongly to the surgeons who think with Desault "that the simplicity of an operation is the measure of its perfection." A needle and thread are always at hand. A few days after the operation the result has declared itself and no anxiety is felt regarding the passage of the button through the intestines, or lest it may leak, or cause ulceration or sloughing, or become plugged with fæces. On the other hand, when suture fails it is usually due to bad sewing, as I think was the fact in one of my own cases. Those who sew cannot comfort themselves by blaming the button, or the bobbin, or the plate. The chief objection to sewing is the time it takes. But the time can be much shortened by careful organisation and by skilful rapidity, and shock is now less severe as hot tables are used and hypodermic injections of strychnine are given and brandy is administered by the rectum. Anæsthetics, too, are now used with much greater skill.

LEEDS GENERAL INFIRMARY.

A CASE OF PERINEAL ABSCESS; PYÆMIA TREATED WITH ANTI-STREPTOCOCCIC SERUM; RECOVERY.

(Under the care of Mr. LAWFORD KNAGGS.)

IN the following case the anti-streptococcic serum was employed with a most satisfactory result. No doubt at the present time the serum is given in many instances where it would not be thought to be indicated if all the facts which might be elicited were known. Only few hospitals possess the equipment which enables general bacteriological work in connexion with cases in the wards to be carried out with promptitude, and as time in severe septic infective diseases is often of great importance the surgeon naturally feels that he must not delay the use of a remedy which may be powerful for good if used in time and which fortunately does not as a rule seem to do harm in inappropriate cases. For the notes of the case we are indebted to Mr. J. Victor Hartley, house surgeon.

A man, aged forty-three years, was admitted on Feb. 9th, 1898, with a perineal abscess of unusual size, which formed a prominence in front at the root of the penis and had burrowed into both ischio-rectal fossæ behind. There had been no retention of urine, but the urethra was found to communicate with the abscess cavity through an opening 1 in. long the result of sloughing. Subsequent progress was uneventful until March 29th. At this time the perineal wound was small and Lister's metallic sounds were being passed daily. On March 29th No. 9–12 was passed for the first time and caused a little bleeding. In the afternoon the patient had a rigor and his temperature rose to 103·6° F. The next day the scrotum was œdematous and a second rigor occurred at 8 P.M. (temperature 104°). On the 31st a considerable quantity of pus escaped from a closed drainage-tube wound at the root of the penis. After this the scrotal condition quickly settled down and gave no more trouble. There was a third rigor on this day (temperature 103·6°). On April 1st he had a fourth rigor (temperature 106°) and an abscess began to form over the left olecranon. There were no abnormal sounds in the chest. It was decided to employ the anti-streptococcic serum, but there was some delay in getting it. The abscess was opened on April 2nd. The pus was stained and numerous micrococci were found. On the 3rd the temperature was 105·4° at 10 P.M., and though no rigor was noticed the patient was very ill during the night and sweated profusely. On the 4th the serum treatment was begun, 10 c.c. were injected over the abdomen at 8.30 P.M., shortly before the time at which a rigor was expected. The same dose was repeated every day except on the 6th, 9th, and 16th till the 18th. It never caused any untoward symptom beyond the pain due to the large quantity of fluid injected. About this time rhonchi were heard over both lungs and for several days there was a good deal of bronchitis and cough. There was also marked hæmoptysis, but this was present only on April 5th and 6th. On the 8th the chest condition had almost entirely cleared up, but at the angle of the right scapula sibilant rhonchi and crepitations could be heard over a small area. By the 10th an occasional cough was the only sign of lung trouble left. On the 11th an abscess which had been forming over the outer condyle of the right humerus for three days was opened. From this date the patient mended rapidly, no further local manifestations developed, and an inflammatory patch in the subcutaneous tissue on the inner side of the patella, which was first noticed on April 6th, gradually subsided without suppuration. The excursions on the temperature chart had been steadily but slowly diminishing from the commencement of the serum treatment, and after the 19th never rose above the normal. No serum was given after the 18th. On the 22nd the passage of soft bougies was begun and on the 30th the patient went home with a slight fistula at the root of the penis which quickly closed. He was seen on August 2nd. He was quite well and passed a No. 11 bougie for himself regularly.

Remarks.—The position of the subcutaneous abscesses in the neighbourhood of both elbows suggests a traumatic rather than an embolic origin. In other words, that laceration of capillaries led to minute extravasations of blood containing micrococci. On the other hand, very little doubt was felt that the lung condition pointed to embolic plugging of vessels which would have resulted in metastatic abscesses if the serum had not been given. Abscesses of embolic origin, besides being more liable to occur in inaccessible situations and to interfere with vital functions, point to the existence in the circulation of masses of micro-organisms unable to traverse its smaller ramifications and would seem to indicate that the septic process had reached a point beyond the protective powers of the body to cope with successfully. Here, therefore, the gravity of the prognosis was distinctly increased as soon as the lung condition developed. The effect of the serum upon the chest symptoms was very marked. They completely subsided in two or three days under this treatment alone. When the lung condition, which presumably never reached the suppurative stage, had subsided, and after the progress of an inflammatory focus near the right knee had been effectually checked, an abscess developed near the right elbow and had to be incised. This no doubt was of the traumatic variety. It might be argued that micro-organisms when once outside the circulation are not so easily brought

under the influence of the antidote as those within the vascular channels, yet it must be confessed that the appearance of this abscess, when other inflammatory foci—traumatic as well as embolic—had given way under the influence of the serum, is not easy to understand. There were no rigors after the serum was commenced, but there were the daily elevations of temperature and profuse sweatings which are characteristic of the pyæmic state. These gradually diminished each day and in fifteen days from the beginning of the treatment the patient was convalescent. Had the daily dose of serum not been omitted on two or three occasions this period would no doubt have been shortened.

WESTERN INFIRMARY, GLASGOW.

A CASE OF RUPTURE OF THE PATELLAR LIGAMENT; SUTURE; RECOVERY.

(Under the care of Dr. D. MACARTNEY.)

IT is always difficult to say definitely why in one case a fracture of the patella, in another a rupture of the tendon of the quadriceps extensor muscle takes place, while in a third the ligamentum patellæ suffers. That the patella should be fractured by muscular action it is necessary that the knee should be strongly flexed at the time of the contraction of the muscle and one of the other two lesions is liable to occur if the knee is extended. In the case recorded below it is very probable that the blow on the knee was the real cause of the ligament giving way, for there is no evidence that the rupture resulted from muscular contraction. As to the treatment to be adopted for this rare injury there can be no doubt that an aseptic operation offers the best chance of a thoroughly useful limb; for the ligament is even less likely than a fractured patella to unite after having been torn in two.

A man, aged fifty-four years, by occupation a lamp-lighter, was admitted to the Western Infirmary, Glasgow, on Dec. 4th, 1895, suffering from the effects of a fall from his ladder on to the pavement, his knee striking the ground first. On examination the patella was found to be quite normal in shape and size, but drawn up the thigh for nearly two inches, leaving a distinct hollow at the upper part of the tibia. The patient could not extend the limb, and the swelling in and near the joint was well marked. The limb was fixed temporarily on a long splint in order to allow the effusion into the joint to pass away. A week after admission (Dec. 11th), the patient being under chloroform, a vertical incision was made over and below the patella of sufficient length to expose the parts. It was then found that the ligament with the capsule of the joint was torn across in its whole breadth in a ragged line just below the apex of the patella. The under surface, the capsule of the joint, was first dealt with by paring the irregular edges with scissors and uniting the pared edges by means of a fine continuous catgut suture. The ligament proper, which showed the same raggedness of edge, was similarly dealt with, the suture being of the same material but stronger. The parts having been cleaned the superficial vertical wound was brought together by means of salmon-gut sutures, dressings were applied, and the limb was fixed in an osteotomy splint, which was raised on a block when the patient was put to bed. For a day or two he complained of pain and uneasiness, but as his temperature kept normal it was thought right not to disturb the dressings. On the 20th, nine days after the operation, the dressings were removed and the wound was found to have healed; half of the stitches were removed. On Jan. 7th, 1896, the splint was removed. On the 22nd the patient was allowed to get up and two days later was permitted to go home. Four months afterwards he visited the infirmary to report himself. The limb was quite well, the patella was in its proper place and his walking was good. He had resumed work and felt no difficulty in the use of his injured limb.

Remarks by Dr. MACARTNEY.—Rupture of the patellar ligament is of comparatively rare occurrence, and on that account alone the record of such a case is interesting; all the more if the steps taken to treat the condition showed more clearly the pathological state of the parts involved, which the case described above did. In such recorded cases as I have come across in my reading the rupture has been near the tibial insertion; in some cases the ligament has torn away its bony attachment. In Holmes's "System of Surgery" cases recorded by Spence, Chiene, Toogood, and Shaw are referred to. In only one of these—namely, that reported by Shaw—has the rupture been at the patellar end of the ligament. The thing which struck me as being most noteworthy was the stringy, ragged appearance of the wound in the ligament.

Reviews and Notices of Books.

Die Zelle und die Gewebe. Zweites Buch von Professor Dr. OSCAR HERTWIG. Mit 89 Abbildungen im Text. (Cell and Tissue. Second Book. By Professor OSCAR HERTWIG. With 89 Illustrations in Text.) Jena: Verlag von Gustav Fischer. 1898. Pp. 314. Price 7*s*.

THE author having in a previous work given an account of the chemical, physical, morphological, and biological characters of the "cell" now takes up the physiological side of the process of development, dealing especially with the mode of origin of the tissues and the physiological causes of the formation of the structures and organs of the body. He shows how the cells unite to form the individual, the mutual influence they exert upon each other in point of physical characters and function and the mode in which they become differentiated for the performance of the duties they have to discharge. He shows how cells respond to external agents and that even in the case of the ovum the process of development is not a mere unfolding and increase but that the ultimate product is the result of the action of many external and involved factors, that variations of temperature, of light, and of food in the earlier stages exert in different instances potent influence on the growth, external characters, and life of the adult. Thus, in the matter of temperature he gives drawings of four ova of the frog respectively kept for three days at a temperature of 10° C., 15°, 20°, and 24°. In the first the ovum is shown to have only reached the gastrula stage, in the second the medullary plates are seen to have formed, in the third the primary gills appear with the rudiment of a tail, whilst in the fourth the external branchiæ are fully formed and the tail has attained considerable length. Similar effects of variations of temperature are seen in the seasonal dimorphism of many butterflies, quoting the interesting observations of Professor Eimer upon a little butterfly, the Lycæna agestis, which is widely spread and which exhibits dimorphism in accordance with the season. In Germany the insect has a winter and a summer form, which may be designated A and B, but the same insect appears in Italy also with two seasonal forms, B and C. The form B thus appears in both climates, but in Germany it is the summer and in Italy the winter form. The German winter form does not occur at all in Italy whilst the Italian summer form does not occur in Germany. Hence it may be concluded that the various forms are associated with variation of temperature.

So with chemical agents, the differences presented by flowers growing in different soils is well known to gardeners. Iron, Professor Hertwig points out, is essential for the formation of chlorophyll by plants; without this element chlorosis supervenes and if it be then supplied indications of recovery become apparent in 24 hours. So Knop found that on feeding plants of maize with certain sulphites the resulting form was so different from the ordinary one that it might quite easily have been described as a new species. Nor is the influence of chemical agents less obvious in the case of animals. The effects of arsenic and phosphorus fumes are the subjects of present legislation, and the fact that the absence of lime is a fertile source of disease is familiar knowledge. The changes caused by an increase or decrease of salt in the brine

Digitized by Google

shrimp Artemia, the alteration effected in Whitstable oysters when transported into the Mediterranean, the influence of exclusive feeding of certain butterflies on lactuca or on atropa belladonna in changing their colouration, the practice of modifying the colouration of the feathers of certain birds by the natives of the Amazons by the substitution of the fat of some kind of fish for their ordinary food, the effects of small quantities of lithium on the development of the larva of sea urchins and of the changes effected in development of frogs' and 'axolotls' ova in a 6 or 7 per cent. solution of common salt, in the production of anencephaly and hemicrania, with many other facts, are collected in a very interesting manner. The subject of the influence of the internal factors of organic development is treated with equal fulness of detail.

Professor Hertwig concludes his work with a short account of the different theories that have been advanced since the appearance of Darwin's book and finishes with the following account of his own views, which we have taken the liberty to slightly abbreviate: The cell with its properties is the elementary living being; it is the carrier of the idioplasm and thus corresponds to Herbert Spencer's "physiological unit"; owing to its collective activity it brings forth the different kinds of plants and animals. Inasmuch as all organisms in the course of their development pass through the one-celled condition the cell must possess in their simplest form all constant and essential characteristics by which the several species are differentiated. There are therefore as many fundamentally different kinds of cells as there are different species of plants and animals. The essential character distinguishing these different cells are hidden from our knowledge; we can only on logical grounds presume that the cell possesses an extremely delicate organisation, and that the highly organised substance which determines the species of cell and was called "idioplasm" by Nägeli is only a small part of the total cell substance and, on Professor Hertwig's hypothesis, is included in the nucleus. The agreement between the different individuals of each generation or the continuity of development is effected by the circumstance that every individual proceeds from a single cell. The question then arises how out of the cell and its invisible peculiarities the compound organism with its visible peculiarities proceeds. And the answer given by biogenesis is that it is through the multiplication of the specific cells and the coincident processes of social union, division of labour, and integration. A physiologically fundamental character of every form of life is the faculty of preserving its kind, which is owing to the fact that each cell by hereditary division gives rise to innumerable generations of cells which are carriers of the peculiar characters of the race or of the 'heredity mass.' These cells or units take specific forms which at every stage show the influence of, and are modified by, countless external factors as well as by the endless complications which the life units exert upon each other. The individual cells, although of the same species as being descendants of the same mother cell, yet develop under dissimilar conditions both in point of space and of time. The full exposition of Professor Hertwig's theory requires more space than is at our disposal, but our readers will be able to gather from the above the general tenour of his work.

Elements of Pharmacy, Materia Medica and Therapeutics. By WILLIAM WHITLA, M.A., M.D. Seventh edition. London: Henry Renshaw. 1898. Price 10*s.* 6*d.*

THE issue of a seventh edition of Dr. Whitla's well-known work is itself strong evidence of its popularity, and the present volume, which is brought well up to date, will be found a useful addition to the library of all students and practitioners. The book is divided into five parts. The first part is devoted to the subject of pharmacy, and full directions are given concerning the compounding and dispensing of drugs. There are numerous woodcuts which illustrate many practical points, and the "general hints to the dispenser" at the end of the section will be found equally useful to the prescriber.

The administration of medicines is dealt with in the second part and the subjects of variations of doses, incompatibles, and prescription writing, are all carefully considered and fully explained. In connexion with the last-named subject there is a very useful table which gives all the Latin words which are ever likely to be met with in prescribing.

Materia medica occupies the third part, and here the arrangements and classifications of the different preparations in tabular forms will be very serviceable to students for examination purposes; there is also a description of all the official remedies arranged in alphabetical order. The important subject of therapeutics is considered in the fourth part, and here again the drugs are arranged alphabetically. Clear and concise accounts of their actions are given and examples of typical prescriptions are freely interspersed.

The fifth part is given up to non-official drugs and a judicious selection of the principal ones in use together with their therapeutical actions will be found.

A valuable index of the poisons and their antidotes, lists of the additions and omissions of the British Pharmacopœia for 1898, and full tables of the weights and measures together with the relations between English and metric weights will also be found. It will thus be seen that the different branches of the subject are all fully dealt with in a useful and practical manner and the book is one which can be confidently recommended to both practitioners and students.

Renal Growths, their Pathology, Diagnosis and Treatment. By T. N. KELYNACK, M.D. Vict., M.R.C.P. Lond., Pathologist to the Manchester Royal Infirmary; Demonstrator and Assistant Lecturer in Pathology at the Owens College, Manchester. Edinburgh and London: Young J. Pentland. 1898. Pp. 269. Price 12*s.* 6*d.*

IT is a very fortunate thing for teachers and workers in science that able men are from time to time inspired to write monographs. It is mostly a labour of love, and though the financial profit may not be large the credit is considerable when the result is as successful as in the present case. The subject of renal growths, which Dr. Kelynack has chosen for a monograph, is a difficult but highly interesting one. No one in this country has hitherto attacked it and Dr. Kelynack has done so in such a thorough manner that he has filled a gap in medical literature for some time to come.

In an introductory chapter the author points out the vague nomenclature formerly in use with regard to renal neoplasms—rendering the records of the past almost valueless for purposes of scientific study. Accurate histological data have only begun to accumulate within the last few years, the term cancer having been loosely employed for any sort of malignant growth of the kidney. The classification which Dr. Kelynack prefers is that of Newman, which differs from that of most writers on the subject in disregarding the question of congenital or acquired origin and taking histological structure alone into consideration, and this is certainly a logical position, since there is no hard and fast line between the renal tumours of infancy and of adult life. Numerous figures are given illustrating the frequency of primary and secondary growths of the kidney, but the number of cases with an accurate histological record is not sufficient for any satisfactory conclusion as to the relative frequency of the different types of neoplasm. Secondary growths appear to occur in the kidney in some 8 per cent. of all cases of carcinoma and in 14½ per cent. of all cases

Digitized by Google

of sarcoma. In the matter of etiology Dr. Kelynack is unfortunately not in a position to shed much fresh light on the subject. Embryonic inclusions of different kinds receive due consideration and a number of cases are recorded in which traumatism seems to have preceded the appearance of the growth. The author's own figures as to the influence of sex are in opposition to those of most authorities, as he finds a slight preponderance in females up to the age of forty years, and this seems to be due to the larger number of cases of sarcoma in early life in that sex. In an analysis of 160 cases of malignant renal growths of all kinds their excessive incidence in early childhood is well brought out, 52 per cent. occurring in patients under ten years old.

A chapter is devoted to the general characters of renal tumours; in some tables devoted to their weight the greater average mass of sarcomata, as compared with carcinomata, is well brought out as also is the greater average mass of cases in children compared with adults. Size, form, and consistency are also discussed. The surgical importance of the modes of extension of malignant renal growths leads to a special chapter devoted to this subject and several important points are brought out, amongst others the lateness and comparative infrequency of lymphatic involvement and the liability to spread along the veins. It is a well-known fact that renal tumours are often extremely difficult to diagnose microscopically and there is probably no organ in the body of which the neoplasms would better repay minute study than the kidney. Regret may be expressed with regard to the brevity of Dr. Kelynack's chapter on the Relationship of Renal Growths, and the absence of any definite conclusions on the subject. We can, however, fully endorse his remark that sections should be prepared from different parts of any doubtful growth, as the microscopic appearances may vary remarkably in the same neoplasm.

The benign growths of the kidney are naturally treated shortly on account of their relative rarity and slight practical importance. Fibroma, lipoma, and angioma are the principal forms described. An interesting case of fibro-lipoma is quoted at length from Warthin and another of a very unusual case of vascular growth from Rolleston and Kanthack. Renal sarcoma is very fully considered, since it is perhaps the most important and in many respects the most interesting class of renal growths. The author deals with them from three points of view—according to the age at which they develop, the situation in which they arise, and their histological character. A summary of all the known facts is well presented, though nothing of any striking novelty is to be found. The complex histological character of many of the renal sarcomata is very rightly insisted on and cases of myosarcoma and adenosarcoma are related. Next follows an account of the adenomata, simple and malignant; the writer lays stress on the occasionally malignant character of certain growths which from their microscopic characters alone might be pronounced innocent. A full account of a case of "malignant papilliferous cyst-adenoma" is given, with clear and careful drawings, and other cases are related for comparison. The very important question of the relation of renal growths to adrenal structures is the subject of a special chapter. The inclusion of adrenal "rests" not only in the kidney but elsewhere is a well-established fact and there are numerous examples of renal growths which seem clearly to have this origin. The best authenticated of these are described by Dr. Kelynack in considerable detail and he is able to add cases under his own care. True carcinoma of the kidney is dealt with in a comparatively short chapter, a circumstance due mainly to our ignorance of these growths. Not only is there no hard and fast line between adenoma and carcinoma, but the truly epithelial growths of this organ are often very difficult to distinguish from those of connective tissue origin. Nevertheless, true cancers are not very rare and Dr. Kelynack is able to quote examples of their most important varieties.

The relation of renal to adrenal tumours is so close that the author very properly devotes a chapter to the growths arising in the latter organs. Of the benign growths adenoma is the only one of any importance and numerous illustrations of this condition are given. Various malignant tumours are also described, including a full account of a case of primary adrenal sarcoma by Affleck and Leith. Finally, a short account of perirenal growths ends the pathological part of the volume and deals mainly with perirenal lipomata.

It is sufficiently evident that Dr. Kelynack is a pathologist, for after 191 pages of pathology we find symptoms, diagnosis, and treatment disposed of in less than 40 pages. Not, indeed, so much because he omits anything, for we can find no matters of importance left on one side, as because this part of the subject seems to appeal to him less and he only rarely introduces illustrative cases in any detail. We note with pleasure that the old doctrine that renal tumours do not move with respiration receives very qualified acceptance at the writer's hands; small degrees of movement, at least, are common. The differential diagnosis of renal growths from other tumours with which they might be confounded is discussed with sufficient fulness. In treatment the all-important question is whether removal is justifiable or not. The history of the operation is given and its mortality from various published tables carefully considered. Dr. Kelynack does not take by any means so pessimistic a view as to surgical interference as is usually met with. He believes that the present mortality (some 50 per cent.) might be largely reduced if the operation were undertaken at an earlier stage than is commonly the case. A long and useful bibliography of thirty pages and a good general index bring the work to a conclusion.

Dr. Kelynack may be congratulated upon the care and thoroughness with which he has brought together and rendered conveniently accessible such a large mass of information upon an important and interesting but difficult subject. The only important matter to which we can take exception is that the book is too largely a collection of the observations and opinions of others and too little a judicial criticism of those opinions by the writer himself. This, however, is a small matter compared with the great service which Dr. Kelynack has rendered in writing the monograph. The illustrations are numerous and often admirable. Mechanical reproductions of photographs are largely employed, but they are not invariably successful in giving a good idea of the naked-eye characters of a renal growth since the colour element is wholly lacking—indeed, some of the most instructive illustrations in the book are from drawings and not from photographs.

ROYAL AQUARIUM, WESTMINSTER.—At the Royal Aquarium there is now on exhibition a family consisting of Clara, Tom, and Anna Snell, three of a family of fourteen. They were born at the Bunyip, Gippsland, Victoria, their father and mother being natives of Devonshire and showing nothing of the extraordinary peculiarities of their children. The rest of the members of the family are of normal size. At the age of twelve years Clara, the eldest, weighed 17 st. 4 lb., with a waist of 66 in., calves 23 in., and arms 19 in. Tom at the age of eight years weighed nearly 9 st. and Anna turned the scale at 8 st. 4 lb. Clara is now twenty-four years old, weighs nearly 36 st. and measures 78 in. round the waist, 26 in. round the leg, and 22 in. round the arm. Tom, aged twenty years, weighs 19 st. and measures 48 in. round the chest, the rest of the body being very well peveloped, and Anna, the youngest, turns the scale at 24 st. and is large in proportion, their united weight totalling nearly half a ton.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 17, 1898.

RICH in moral as in material products Italy seems bent on creating a monopoly in that most sinister creature—the political assassin. Her soil is traditionally well fitted for his cultivation. Given the southern blood, quick to feel and quick to resent; given the all too amply justified contempt for the law as a means of protection and reparation; given the much-abused resource of the confessional, which whitewashes crime and rehabilitates the criminal on easy terms; given the sonorous rhetoric of the Revolution with its impassioned appeals only too effective with an impressionable proletariat, to the examples of HARMODIUS and ARISTOGEITON, of TIMOLEON and BRUTUS, of BALILLA and PALAFOX; given finally the hardness of living which makes incarceration welcome and meets death more than half way, and we have a total of conditions which goes far to explain the fact that, "excluding Spain and Portugal, Continental Europe is outdone in her annual number of homicides by Italy alone," and that Italian soil is rapidly becoming the appropriate recruiting-ground whence the political assassin springs — whence he is almost invariably drawn to subserve the purposes of aggressive Socialism and to promote the Reign of Terror which the anarchist avowedly seeks to impose.

For this characteristically Italian "product" has now become an Italian "export"—freighted from Italy in unusually increasing numbers, represented in the gangs of cheap labour which the hardness of living within her borders throws year by year upon frontier States and even further afield, until there is hardly a European centre which has not its "Italian quarter," lost to its own and not affiliated to its adopted country and only too prolific of desperadoes, the willing tools of the "social vendetta." Leaving out the attempt in Rome during the race week of last year on the life of King HUMBERT, the three murders within a few months of each other of the French President CARNOT, of the Spanish Premier CANOVAS, and now of the Empress of AUSTRIA have each been the work of an Italian, each perpetrated with a cynical audacity bearing a perfect family likeness, and each gloried in by its author as, though possibly useless in itself, still done "*pour encourager les autres*" and preparing for the "socialist advent" and for the "anarchical paradise."

The political assassin is indeed an Italian "export," and Italy must not be surprised if the civilised world applies to it the most stringent prohibitive "duty" if only in self-defence and the common interests of mankind. Already the European press is recommending as strict a frontier surveillance over the immigrant Italians as is already enforced against the unauthorised importation of dynamite or any other death-dealing explosive, and it justifies this policy on the ground that it is humaner and less likely to irritate than the hounding to death of Italian residents or the sacking of Italian shops which was practised on French soil after CASERIO'S murder of CARNOT. Even without such preventive policy it is likely enough that Continental employers of labour will shrink from recruiting their industrial hands from Italy and thereby introducing into their respective communities an element so prompt to make itself the tool of a conspiracy aimed avowedly at all wealth amassed through the toil of others. But be all this as it may, the lesson must be borne in upon Italy herself that it is with her and her alone that the responsibility lies of sinister "product" and sinister "export" alike and that only by her ceasing to create the former can she hope to escape the consequences which she incurs from the latter. Her whole system—governmental and administrative—requires root and branch reform and she has not a day to lose in beginning the work of rehabilitation. She has representative institutions: let her see that they are properly utilised. She has what practically amounts to manhood suffrage: let her show, or, at least, try to develop, that "sense of citizenship" which on election day brings the voter to the urn, and the want of which, even in the gravest political crises, causes her to poll but half her strength. She has an army and navy far beyond her needs, certainly far beyond her power to maintain at a decent standard of efficiency: let her reduce both to the dimensions required by prudence and the claims of more vital interests. Above all, let her wipe away the reproach cast upon her by her own sons, "che in 38 anni di governo nazionale l'Italia abbia fatto nulla, propriamente nulla, per l'educazione delle classi lavoratrici" (that in 38 years of national government Italy has done nothing, literally nothing, for the education of the working classes). Here, indeed, lies the inner plague spot of her political system—the impoverishment of her elementary and secondary schools to meet the expenses of establishments which devour her substance and drive her robuster hands to seek a livelihood in other climes. Out of a population of (in round numbers) 30,000,000 about one-half are *analfabeti* (unlettered), and this too when, thanks to her thirty universities, her professions are enormously over-manned, 500 *avvocati* (barristers) thrown upon the public every year in excess of any possible occupation for them, and medical men "duly qualified" in similar disproportion after a four-years' graduation course which costs only three hundred francs (£12)! By none is this "waste" or malversation of intellectual and moral force more deeply deplored than by the heads of the professional classes themselves, condemned as they are to see the unemployed *avvocato* or *sanitario*, whom nature intended for industry or commerce, seeking in political agitation or revolutionary journalism the maintenance his all too easily acquired degree denies him. "Heal thyself," is Italy's watchword, and she may rest assured that in the Europe (justly indignant at her unique reinforcement of anarchical crime) which is now striving to protect itself against the assassins whom she exports she will find a sympathetic

Digitized by Google

well-wisher and auxiliary if only she will be true to her illustrious traditions and rehabilitate herself on nobler lines.

THE exceptionally dry and bright weather which has been experienced in this country during the summer months, culminating in the heat waves which have not yet ceased to beat upon us, has brought with it both benefits and ills. Of the latter the scarcity of water in many rural districts and in the most densely populated sections of the metropolis has been perhaps the most prominent. Happily, it has not as yet been accompanied by any notable increase in sickness, whilst as if to compensate for the drought the farmer has had no reason to complain of the character of the harvest. Setting aside the important question of water-supply, which is dealt with in another column, it may well be asked whether a hot season does not conduce more to health than to illness provided that due provision is made by those subjected to it to accommodate themselves to the change in temperature. For with heat comes the excess of sunshine which, as we all know, is one of the best of Nature's remedies. [A summer like that which we have just gone through has enabled thousands to live practically in the open air and to gain fresh vigour of mind and body by the mere subjection to the influence of light, assisted by the breezes from the sea or the pure air of the mountain-top. Many, we doubt not, have prolonged their holiday in some health-giving spot, taking full advantage of the continuance of sunshine, and in this they have acted wisely by adding still more to their stores of health.

All, however, are not so happily circumstanced, and the vast majority of our town-dwellers are those who have had perforce to remain chained to the mill and to pursue their daily task under conditions which are, to say the least, irksome. Yet even to them life under exposure to well-nigh tropical conditions would have been endurable had they only been able to change their habits with their environment and temporarily to transfer to the temperate regions the manners and customs of the denizen of the tropics. Few, however, can do this—many because of the lack of enterprise or of the dread of making any change in routine. It is partly, if not mainly, in consequence of this inability to adaptation to circumstances that every "heat wave" is sure to be marked by cases of sickness directly due to the heat itself. Nor are such cases all of the category of heat-stroke or heat-apoplexy of which there have been not a few during the past weeks. Sometimes the influence of heat has been exerted on the brain in such a way as to produce definite functional derangement and undoubted insanity. It would seem, indeed, as if the higher cerebral functions are especially prone to be affected by extremes of temperature. We imply this when we say that cold benumbs and heat exhausts the faculties. Intellectual labour of any kind is toilsome under extreme climatic conditions, and much of the differences in racial characteristics, both physical and mental, may be explained by the nature of the climate under which life is carried on. That there is evidence of the direct action of external heat upon the production of insanity is manifest from the comparative frequency of a history of previous sunstroke amongst the insane in contrast with the prevalence of sunstroke in the community at large. No doubt the "sunstroke" is only one factor towards the ultimate result, but it is equally certain that often everyone of the antecedents may co-exist without the sequel of insanity. Yet it is probable that many of those who do become insane after experiencing a sunstroke have become so in consequence of some pre-existing mental instability.

But does this explanation hold in such cases where the mental derangement follows immediately upon the heat-stroke? Of this there have been several cases recorded during the past few weeks—cases of acute mania, of melancholia, of suicide—of which no other explanation has been forthcoming. The scientific investigation of such cases has yet to be made, but the fact remains that exposure to unaccustomed heat may upset the nervous balance so that what to one is merely a sense of exhaustion or an irritability of temper is to another pronounced insanity. Curiously enough, it is not amongst those whose nervous organisations are the most finely balanced that these graver effects are most often shown, so that it is clear the subject requires far more attention than has hitherto been bestowed upon it. It comes to this, that in a temperate climate like ours the subjection for even a few days to a temperature of 90° F. in the shade is trying to all and dangerous to some. It might be better borne and its dangers minimised were it possible for the community to change their habits and their clothing concomitantly with the rising thermometer. But duties have to be performed, the imperious behests of fashion have to be obeyed, the daily routine of work has to be gone through, and the staple articles of food consumed in order that the machinery of our civilisation shall continue to do its work without fail. Hence it happens that more victims have to be sacrificed to the sun-god than he would be able to claim were more rational modes of living in vogue. Still, in spite of all there are few who do not gladly suffer the inconveniences and discomforts of a temporary tropical existence under conditions adapted to the temperate zone in return for the gain to health which must accrue from a high average of the number of hours of sunshine.

WHILST the physics of the senses of sight and hearing have attracted the attention of many philosophers and have been elucidated by numerous ingeniously contrived experiments those of taste and smell have been comparatively neglected. The very phraseology by which we are accustomed to describe the impressions which we receive through these portals of sense is indefinite, obscure, and uncertain. There are, indeed, several terms which would call up corresponding sensations in regard to the sense of taste, such as sweet, acid, alkaline, oily and mawkish, but our vocabulary is small in calling up sensations of smell and is almost limited to such general terms as pleasant and unpleasant, pungent and aromatic, fœtid and fresh, which have none of the definiteness or precision that the terms blue or green possess in ordinary conversation or that the expression treble G gives to the musician. Our memory of odours is in general very imperfect. Attempts have been

Digitized by Google

made, but not very successfully, to establish a gamut of odours, and it is difficult in many instances to dissociate the senses of smell and taste. CUVIER observed that these two senses are nearly allied to common sensation. In those animals which are only capable of breathing through the nose, like the horse, the extent of surface ministering to the sense of smell is immense as compared with that of man. A large area of the nasal cavities is covered with mucous membrane which is thick in both, studded with numerous acinous glands, covered with stratified ciliated epithelium, supplied by the fifth pair of nerves, and is probably dedicated to other functions than those of smell, as for example, the warming and moistening of the air,' and its purification from dust before entry into the lungs, and a large portion also of the upper region seems merely to act as a periosteum to the frontal and ethmoidal cells, and to possess but a small share of special sensibility. The turbinal bone, on the other hand, the volutes of the ethmoid, and a considerable area of the septum between the nostrils, is covered with a thin yellowish-red membrane, the epithelium of which is unprovided with cilia, to which the branches of the olfactory nerves are distributed, the ultimate fibrils being traceable to the very surface, covered only by a thin layer of fluid and being well placed therefore for the perception of delicate impressions. Common observation shows that whilst man is capable of perceiving a great variety of odours many animals surpass him in the acuteness of their perceptions. The nature of these emanations probably varies considerably. Water, which has no smell to man, can be perceived by some animals at considerable distances. Sexual odours appear to be peculiarly expansive. SCARPA found that if he plunged his hand into water after handling a female toad the males were attracted to him. Insects, and especially those of nocturnal habits, are guided to each other by their emanations. Judging from the actions of animals, the odours of plants are only in rare instances, as in the case of valerian by the cat, perceived or at least enjoyed by the carnivora. Putrid meat is devoured by the vulture and jackal though it is not touched by many flesh-eating animals that feed on living prey, whilst it produces a kind of convulsion in many horses and madness in the bull.

The physics of smell was made the subject of an address delivered to the British Association at Bristol by Professor W. E. AYRTON, F.R.S., who has devoted much time to the subject and has performed some original experiments. The points to which Professor AYRTON especially directed his inquiries were the smell of metals, the rapidity with which odours diffuse, and the capability of odours to traverse thin films of glass. In regard to the first point it seems that contrary to what might be expected a large number of the metals, as aluminium, copper, silver, gold, iron, steel, tin, and zinc, and of the alloys brass, bronze, German silver, and phosphor-bronze, have no smell, providing they are carefully cleaned, nor is any smell perceptible when they are rubbed over with dilute nitric acid, vinegar, ammonia, soda, or a solution of sugar, except the odour of these several substances. Breathing on brass, copper, iron, steel, or zinc, which has been rendered practically odourless by cleaning produces a very distinct smell which Professor AYRTON is inclined to believe is due, when iron or steel is handled, to the hydrocarbons developed by this operation and not to the detachment of particles of the metal.

In regard to the diffusion of odours it would at first sight appear that odours diffuse with great rapidity. If the females of certain moths be exposed in an open space enclosed in a muslin bag the males will soon be seen to congregate around them. Deer, dogs, and other animals, will recognise their enemies or their prey at considerable distances, but Professor AYRTON, although beginning his experiments with this preconceived idea, and using at first tubes 15 ft. or 20 ft. long, soon found that if draughts were carefully avoided odours diffused with extreme slowness and that tubes of a few inches in length were quite sufficient to enable him to determine the rate of diffusion, from which the conclusion may be drawn that under ordinary circumstances the movement of the air is the principal agent in the diffusion of odours. The long retention of certain odours by glass vessels led Professor AYRTON to try whether an actual transpiration through glass could be detected by the nose, and for this purpose various scents were enclosed in extremely thin glass globes, but the results were negative. The subject which Professor AYRTON brought before the British Association is one of considerable interest, and he deserves the thanks of biologists for suggesting a fresh line of inquiry.

JUST a year ago there began the epidemic at Maidstone in which, during four months, 1818 persons out of a population of about 34,000 were attacked by typhoid fever and some 130 deaths ensued. It will be remembered that the Local Government Board hit upon a novel, and we hardly think a satisfactory, method of investigating this outbreak by means of a formal public inquiry held after the epidemic was over. With the enviable leisureliness which characterises the appearance of official publications they have now issued the report of the three inspectors to whom this inquiry was entrusted. From this report, which we notice in another column, we find that the conclusions drawn by the inspectors are in general accord with the views which at the time of the outbreak were formulated by Mr. M. A. ADAMS, the medical officer of health of Maidstone, as well as with the facts set out in the series of articles by our Special Commissioner published in THE LANCET last October.

The epidemic, say the inspectors, "was caused by the pollution of the water supplied by the Maidstone Company from their Farleigh sources." To a material, but nevertheless to a wholly subsidiary extent, the epidemic once set going was maintained by a multiplicity of insanitary conditions in the town itself—defective drainage, accumulations of excreta in water-closets without means of flushing, and the like. The evidence which connected this outbreak with water was irresistible. The map of Maidstone could be divided into three areas of peculiar shape, each having an independent water-supply obtained respectively from the springs of Cossington, Boarley, and Farleigh. During the first six weeks of the outbreak

Digitized by Google

some 1560 persons in the borough were attacked. If anyone unacquainted with the conditions of the Maidstone water service had set himself to mark on a map the streets in which these people lived he would have produced an almost complete plan of the distribution of the Farleigh service. This peculiar incidence, by far the most important factor in the etiology of the outbreak, was, apart from water, incapable of adequate explanation. It is true that the water company were fortunate in having in Professor CORFIELD a high authority for asserting that notwithstanding the distribution of the cases faulty sewers and house drains might have been sufficient to cause the epidemic. But the suddenness of the outbreak; facts such as the heavy incidence of fever in Barming Asylum, with drains practically without defects, but supplied with water from Farleigh; the special selection by the fever of those (unsewered) parts of the rural district which received Farleigh water, as well as many other matters which the inspectors record, all suffice to show that a theory of infection by sewer emanations could not account for the principal phenomena of the epidemic. In the matter of bacteriological evidence, again, the water company were able to claim some divergence of expert opinion. But the circumstance that Dr. SIMS WOODHEAD, the bacteriologist called in by the company, failed to find bacterial evidence of fæcal pollution in any part of the Farleigh supply loses most of its significance when we learn that all the samples which he examined were collected nine weeks or more after the outburst in the middle of September. And, on the other hand, while the epidemic was at its height, Dr. J. W. WASHBOURN had found unmistakeable bacterial evidence of pollution in certain of the springs, while as late as Oct. 19th Dr. H. E. DURHAM found the bacillus coli in samples which he examined. Moreover, in the circumstances the question whether antecedently to the outbreak there had been dangerous pollution of Farleigh supplies was not one which needed to be decided upon bacteriological evidence. On this point the history of the source of the Farleigh springs, together with the evidence of trustworthy eye-witnesses, which "showed clearly that the neighbourhood of some of the springs was immediately before the outbreak plentifully covered with human excrement," was of itself conclusive. By whose means and at what point or points the specific infection was introduced, the inspectors have, however, been unable to pronounce.

The experience which Maidstone has so dearly bought has, we may hope, already brought some share of good as well as of evil. Throughout the kingdom it has compelled attention to the inadequacy of control which both central and local public health authorities have over water companies and to the pressing need that a proper control should be exercised. For the present state of things Parliament has been largely to blame and Ministers will take heavy responsibility if they delay to find adequate remedy. The outbreak has brought home, as nothing but a big calamity can, the necessity of constant vigilance on the part of all purveyors of water, whether they be local authorities or companies, to safeguard the purity of their supplies. No water authority should rest content with the knowledge that its waterworks are well designed and that at the time of their establishment they furnished water of demonstrated purity. The question must constantly be asked whether adequate steps are being taken to keep this water day by day up to its proper standard of wholesomeness. Only in very exceptional cases can a water authority safely dispense with frequent and systematic skilled inspection of their gathering-ground together with bacteriological and chemical examination, also frequent and systematic, of each contributory source of supply. It is to be feared that in the case of too many of our public water-supplies such inspections and examinations are carried out in a perfunctory fashion, while there are still other supplies in which—notwithstanding the experience of Maidstone—no attempt is made to take these necessary precautions.

Annotations.

"Ne quid nimis."

THE LATE EMPRESS OF AUSTRIA.

IT would be hard to conceive a more impressive spectacle than that which confronts Europe and the civilised world at the present time in the person of the nobly pathetic figure of the Emperor of Austria crowned with sorrows superimposed one upon the other. Upon few princes, indeed, has the irony of fate borne so hardly as upon this dignified and benevolent Emperor. It is a pitiful history, turn which way we will. He succeeded to a kingdom shaken by civil war, but by force of character, combined with just and conciliatory rule, he has lived to convert his once bitter and traditional enemies into his warmest friends and admirers. In no part of his composite empire is Francis Joseph so beloved as in Hungary. He has seen the kingdom it was his unhappy fortune to inherit torn and mutilated at Magenta by the victorious armies of France and Sardinia and on the plains of Bohemia by the Prussians at Königgrätz. Turning to the private and domestic side of his character it is benevolent and blameless. The life of the Emperor, who is universally recognised as a good and virtuous man, with a conscience void of offence to everyone, has been full of tragedy—sorrow succeeding sorrow and disappointment following disappointment. But, like the hero he is, he has borne himself throughout with real dignity. He has never allowed his misfortunes to embitter him or render him cynical; on the contrary, they have widened his sympathy with suffering and enlarged his charity. And yet, to quote his pathetic exclamation on hearing the terrible news of his wife's assassination, it seems as if no sorrow in this world is to be spared him. It must be remembered that his marriage with the Empress was a love match; that the Emperor was passionately in love with the young, beautiful and romantic girl who has throughout been his affectionate support for forty-four years and who was an altogether charming, brave and accomplished woman of whom any prince might have been proud. Well might the bereaved Emperor say that it passed his comprehension how a man could lift a finger against his wife who certainly never injured anyone in her life. The womanly graces, the charities, the pitifulness and heroism making up the Empress's life and character were well known. It is, indeed, a lamentable illustration of the irony of fate that at the very time when his subjects are preparing to celebrate the Emperor's jubilee this calamity should have fallen upon him. The Emperor's devotion to his sense of duty has hitherto carried him through all his trials and those

Digitized by Google

who know him best feel assured that it will not desert him now in the hour of his present affliction but that he will maintain the same fortitude he has always displayed. It is some solace to feel that the death of the unfortunate Empress was so comparatively painless that Her Majesty evidently did not realise the injury she had received and that it was so speedily followed by unconsciousness. Of one thing the Emperor must feel assured—namely, that all his subjects share his sorrow and that he has not only their heartfelt condolence, sympathy and respect, but those also of every right-thinking man and woman outside the confines of his empire. As regards the perpetrators of such crimes they are simply outside the pale of humanity and they require to be treated with exactly the same consideration that we should extend to dangerous wild beasts or venomous reptiles, and some concerted international action is required to deal with these cruel pests. The post-mortem examination showed that the heart had been completely penetrated; and some surprise has been felt that so grave an injury to a vital organ can be inflicted without causing immediate death. But unless the cardiac ganglia are directly involved such an event seldom happens, provided that, as in this case, the wound of the heart wall is small, for in medical literature there will be found records of survival of considerable duration with retention of power such as in this case enabled the Empress to walk to the steamer and to be herself unconscious of the gravity of the lethal blow. We publish elsewhere the details of a case of wound of the heart which was successfully sutured eight hours after the injury had been inflicted.

THE LABELLING OF POISONS.

AN INQUEST of considerable importance to medical men and druggists was held by Mr. Cox, coroner for the Exmouth district, on August 15th. The coroner made use of strong expressions, as will be seen below, but it is a matter of regret that he had not first consulted the Pharmacy Acts, when he would have seen that whatever his private feelings may have been he was quite wrong in his law. The inquest was on the body of a child, aged three years, who drank some of the contents of a bottle of eye wash which had been left on a chest of drawers. The wash had been obtained from a druggist (Mr. Bickford) through the dispensary according to a prescription given by Mr. Martyn. The mother had been using the eye wash for some months, but had not been told whether it was dangerous or not. The coroner said that the bottle had a red label bearing the words, "Not to be taken," and another label with the following: "Exmouth Dispensary. The drops to be used three times a day. Lily Bastin. J. T. Bickford, dispenser by appointment, Strand Pharmacy, Exmouth." The lotion was made up from cocaine, atropine, and water. The child when seen by Dr. J. W. Hodgson shortly after swallowing the lotion was suffering from the symptoms of atropine poisoning and died the following day. It is not with these symptoms that we are concerned, however, but with the following conversation as reported in a local paper (*Devon Gazette*, August 16th). Mr. J. T. Bickford stated that he supplied the preparation in the bottle produced. "The Coroner: Are you aware what the ingredients are? Yes.—Are you aware that some of them are poisons and that they are incorporated by the Pharmacy Act in Schedule A as such? Yes.—Are you further aware that it is your business to be aware that any preparation of atropine has to be labelled 'Poison'? No; I am not aware of that with respect to a medical practitioner's prescription. I am aware that if it is sold over the counter it is required to be labelled.—The Coroner: This bottle ought by law—and you have broken the law—to have been labelled 'Poison,' and it is for the protection of the public that that law was made. Did you label it? Yes.—Then you've broken the law and it is a very serious matter for you; you have neglected your duty and this child has died. The regulations laid down in this Act are made for the protection of the public and it is my duty to see that they are carried out.—Witness: Will you read the Act, please? The Coroner: Yes, most certainly.—That part of the Act relating to the subject was read and Mr. Bickford contended that he had complied with the provisions.—The Coroner: I don't know what view the jury will take of this case, but you lay yourself open to a charge of manslaughter and I leave it with them as to the verdict. They can return a verdict of manslaughter if they think it a case of sufficient neglect." Assuming the above to be a correct report of what took place such remarks falling from the lips of an officer of the law are very serious. Turning to the Act we find in Section 17 the following words: "It shall be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article and the word poison, and with the name and address of the seller of the poison." Certain exceptions are then made, such as in the case of a "legally qualified apothecary." We presume it was the above extract which was read in the open court. It would have been better, however, for everybody concerned if the following had also been read: "An Act to amend the Pharmacy Act, 1868, 32 and 33 Vict., cap. 117," "3. Nothing contained in section 17 of the said recited Act shall apply to any medicine supplied by a legally qualified medical practitioner to his patient or dispensed by any person registered under the said Act, provided such medicine be distinctly labelled with the name and address of the seller, and the ingredients thereof be entered with the name of the person to whom it is sold or delivered in a book to be kept by the seller for that purpose." As nothing is reported to the contrary, we may presume that Mr. Bickford followed the usual custom of copying the prescription before sending out the bottle; consequently, by placing the label "Not to be taken" on the bottle, Mr. Bickford took more precautions than the law required and certainly did not merit the reproof administered by the coroner. We hear that the latter has offered an apology for his error. We trust that such is the case and that the withdrawal of the censure will be as widely made known as the report of the inquest. We cannot leave the subject without drawing attention to the verdict of the jury: 'The jury, after a short deliberation, returned a verdict of 'Accidental death,' adding a rider that the cause of death was due to the child drinking part of the poisonous contents of a bottle of eye wash." The foreman (Mr. J. Dyer) also said it was the unanimous wish of the jury that he should say that all druggists in Exmouth, when supplying any of the poisons or preparations in which they were contained mentioned in the Act should label the bottle "Poison." The Coroner (addressing Mr. Bickford): "You have heard the expression of the jury. I entirely agree with it and I hope you will adhere strictly to what has been said and that you will label all dangerous bottles 'Poison.'" A juryman: "I don't think that it is the opinion of the whole jury. It is not mine. I think it is only the foreman's."

DR. NEUFELD.

IT is perhaps not generally known that Dr. Neufeld, who has just been delivered from captivity in Omdurman by the Sirdar's army, is a medical man. *The Times* of September 13th, quotes the following account of his career on the authority of the *Vossische Zeitung*:—

"Karl Neufeld studied medicine at Leipsic University and went early in life to Egypt, following first his profession as a medical man and subsequently as a merchant. At the

Digitized by Google

beginning of the eighties he had a practice at Keneh, Upper Egypt, where several Germans and also natives of his own home saw him. Subsequently he set up as a merchant at Assouan. After the fall of Khartoum and the firm establishment of the Mahdi's power at Omdurman Neufeld seems to have formed a scheme for opening up commercial intercourse with the closed Soudan, for he equipped a caravan with which he proceeded to Berber, which was then in the hands of Osman Digna. The latter sent the German, whom he looked upon as a dangerous spy, to the Khalifa Abdullahi. This was in 1886. Neufeld was condemned to death and was taken to the place of execution. He behaved there so courageously, asking to be executed like a Mahomedan (instead of suffering death by hanging), that the Khalifa was struck and respited him under the gallows. He was taken to the general prison, with heavy chains on his hands and feet, and treated altogether in a most abominable manner. He was kept alive by the women, who took pity on him and fed him, as they had done before him to Slatin. Then an endeavour was made to utilise his knowledge. He knew nothing about founding cannon, but he managed to manufacture powder, and he was also ordered to invent a machine for coining money. Owing to the escape of Father Ohrwalder and, later, of Slatin Pasha, his position became worse. He was again manacled and threatened with having his arms and feet hacked off if he should attempt to escape. There were many efforts to liberate him. The Austrian Catholic Mission, induced by Father Ohrwalder, Slatin Pasha, the British Government, the German, and more especially the Austrian, representatives at Cairo, all endeavoured to further the escape of Neufeld. He frequently received money, but he refused to escape as he would not accept liberty without his wife—an Abyssinian slave presented to him by the Khalifa—and the two children whom she had borne him. The latter would have been exposed to fearful tortures, and thus Neufeld chose to remain a prisoner. He was active subsequently also as an artist, and as he could draw well he was ordered to decorate the mausoleum of the Mahdi, and this pleased the women of the Khalifa so much that they petitioned the latter for his liberation. It is also said that he has written Arabic books and illustrated them. The latter part of his twelve years' detention appears to have been less onerous, as after the escape of Slatin he had to be interpreter to the Khalifa and translator of European newspapers which the ruler of the Soudan received regularly. It is to the credit of the Khalifa Abdullahi that not one of the Christian prisoners received a hurt on the approach of the Anglo-Egyptian forces. It is expected that a narrative of his experiences in the Soudan will be shortly published by Dr. Neufeld."

THE DERBY CORONER AND THE MEDICAL ASSOCIATION OFFICER.

AT an adjourned inquest on the death of William Marshall, aged fifty-one years, a laundry porter of Derby, held by the borough coroner, Mr. John Close, some interesting points were raised, though they were unfortunately obscured by the altercations between the coroner and Mr. A. B. Carey Orchard, L.R.C.P. & S. Edin., one of three medical officers of the Derby Friendly Societies' Medical Association. The facts of the case were very simple and were admitted by Mr. Orchard. They were to this effect: Marshall was found dead in bed on August 19th. He was a member of the Medical Association and had used a prescription written by Mr. Orchard—which was put in evidence—at various times between May 14th and July 2nd. On the prescription he was entitled to three bottles of medicine. When the death occurred Mr. Orchard was away and declined to give a certificate. An inquest was necessitated by this refusal. But the warmth of the altercation began over it and by the other facts candidly admitted and confidently defended by Mr. Orchard. The principal other fact was that Mr. Orchard, the author of the prescription, had no remembrance of having ever seen the patient and thought it quite likely that he had not seen him. He said that on that very day he had done the same thing five or six times. He explained that working men were unwilling to leave their work and often sent a relative to describe the symptoms and get medicine for them. The prescription in question had been written apparently for a supposed slight torpidity of the liver. Another practitioner, Dr. Laurie, testified that his *locum tenent* had seen the deceased and had said that the death was due to heart disease. The report does not show why this gentleman did not give the certificate. Delay of burial and an inquest resulted, at any rate, from Mr. Orchard's refusal to give one. Up to this time our readers will not quite see how any warmth of discussion could arise between two learned gentlemen—Mr. Orchard and the coroner. But it did. The rise of temperature began by Mr. Orchard's saying that the coroner had once abused him for giving a certificate for a patient whom he had attended for eight weeks. It rose as the coroner described the system of the association as one which would allow a patient to be prescribed for for six weeks without being seen by a medical officer, and it culminated when the coroner refused to withdraw an expression of his opinion that the case was "an abominable one," and Mr. Orchard said that he (the coroner) was not a gentleman. He had to withdraw the statement, the coroner having ordered a warrant for commitment to be sent for. It is to be regretted that the facts could not have been temperately discussed, as they really are of interest to the public and all practitioners, and, as we have said, were really very simple. We entirely approve of Mr. Orchard's refusal to give a certificate for a case which he had probably never seen and certainly had not seen for six weeks. Nor can we say that it is absolutely wrong to prescribe for a patient without seeing him. In this work-a-day world it is sometimes inevitable in every class of society and especially in the case of working men. But still some facts of an unsatisfactory nature remain which it was worth an inquest to bring out. Here was a member of a friendly societies' medical association ill for three months and eventually dying without seeing one of its medical officers. We do not say or think that it was Mr. Orchard's fault, but may it not have been the fault of a system which throws on three men an impossible amount of work, and because the medical association system, as its critics say, is only another specimen of that kind of medical practice in which work is done wholesale for crowds and in which the individual patient suffers and perhaps dies? We are passing no partial judgment. The same is true of the out-patient system and even the old club system. And very impartial judgment is needed to correct the evil.

THE DANGERS OF THE "DRY-CLEANING PROCESS."

THE extreme care with which easily inflammable liquids should be handled was exemplified some time ago in the case of a paraffin hair-wash. This unfortunate occurrence, which resulted in the death of a lady from shock and burns, would appear to have been due to the ignition of benzine by the production by friction of an electric spark. It is well known that when the air is particularly dry the production of an electric spark, say by stroking the hair or by rubbing flannel, is a very simple matter. Under the very dry conditions of the atmosphere there is a strong tendency for opposite electrical conditions to exist on the slightest provocation. This probably accounts for a somewhat remarkable accident which occurred in a "dry-cleaning room" at Ashton. Some workmen were engaged in cleaning by the dry process certain garments, such as pants and vests. During the rinsing process a flash suddenly occurred in the "rinse kettle." "It was a bright flash like lightning. Then everything became one mass of flame, the spirit, garments, and everything." The fire extended and one man unfortunately lost

Digitized by Google

his life. The witnesses were one and all positive that the flame had its origin in the "rinse kettle" and every precaution was taken to exclude any possibility of ignition from naked flames or from lighted tobacco pipes. The igniting cause was probably, therefore, an electrical phenomenon and it only remains to suggest that when the weather is remarkably dry the air in dry-cleaning workshops should be kept moist by suitable means and extra care should be taken to avoid friction in the cleaning process.

A FLOATING HOSPITAL SHIP.

THE poor children of New York are during the summer months in a much more pitiable plight than those of London, or probably than those of any large town of the civilised world. The reasons for this state of things in New York are, firstly, because that section of it occupied by the lower classes and termed the tenement district is perhaps the most overcrowded of any plot of a like area in either the Old or New World. Here may be found massed together peoples of all nationalities—Italians, Germans, Russians, Danes, Swedes, Irish, and negroes—existing amidst inconceivably bad insanitary surroundings. The second reason is that there is, owing to the lack of space—New York being compressed within narrow limits by water on both sides—a great need of parks and playgrounds, and the third reason is that the heat during a portion of the summer is excessively stifling and oppressive. Until quite recent times too little has been done by public or private charity and nothing whatever by the municipal authorities towards bettering the conditions of life of the poorer classes in New York. It may be well understood that under these circumstances, while the lot of the adult members of the "submerged tenth" is hard to bear, the infants and young children suffer terribly; indeed, as might be expected, the infantile mortality is extremely high. One of the oldest of the New York charitable associations—St. John's Guild—resolved some twenty years ago to try the experiment of a floating hospital ship as a means of relieving and invigorating sick and weary infants, children, and their mothers during the hot months. Accordingly a boat suitable for the purpose was bought and in 1875 her first trip was made, since which time more than 800,000 children and their mothers have been carried on the Guild's great life preserver. The boat itself is a large barge about 300 ft. in length and having two decks. On the lower deck aft are two wards containing 15 cots and a bed in case some of the children should be too ill to sit outside. A medical man is carried aboard and attends to and gives medicine to any of the little ones needing his medical or surgical care. Forward on the lower deck are situated the commodious bath-rooms, supplied with hot and cold tub baths, shower baths, &c., under the supervision of a head nurse and three assistants. Bathing is made an especial feature of the hospital ship, and taking into consideration the woful lack of bathing facilities in the New York tenement houses the luxury of a good wash in hot water is fully appreciated by mothers both for themselves and their children. The remark, too, need hardly be made that as a sanitary measure and in certain affections the beneficial effects of a sea-water bath is of great value. The upper deck, which is covered in and well-sheltered from sun and wind, has ample sitting accommodation in the centre, but is unobstructed at the sides, thus providing a fine promenade. This upper deck is where the motley crowd of children and women spend their day inhaling the health-giving sea breezes and enjoying a short respite from their sordid existence in their crowded insanitary homes. The catering on the ship is on a generous scale, the infants and small children are given pasteurised or sterilised milk at frequent intervals, while those who are old enough to enjoy a good meal are provided with one in the middle of the day. The dining-room and kitchens are down below. The dining-room will accommodate 350 persons. The food consists of excellent meat stew and bread with milk as a beverage. The officers of the ship comprise superintendent, captain, physician, two matrons, and about twenty nurses and assistants. The total number of women carried in 1896 was 16,934, children 29,370. During the same season 1735 patients received actual treatment in the hospital. Of these 610 received special treatment in the two wards and 1125 on the decks of the hospital. These figures do not include the number of those patients who only received medical and sanitary instruction and advice. It should be mentioned that the ship makes six trips a week, starting at nine in the morning and returning at half-past five, she is able to accommodate comfortably 1600 patients, and in the hot weather is always quite full. Great care is taken by the physician, who examines everyone before embarkation, to exclude all those suffering from infectious complaints, and as the applicants for the trip include many nationalities it is necessary for the medical man to have a good knowledge of modern languages. St. John's Guild has also a hospital for children in New York and a seaside one at Staten Island, distant about eight miles from the city and to this the patients are conveyed by the hospital ship. The seaside hospital and hospital ship receive patients from June to September. Admission to both the ship and land hospitals is granted by means of tickets, which must be signed by a qualified medical man. A ticket for the ship is usually available for the day trip only, but weekly ones are also issued, while the seaside hospital tickets are good for two weeks or longer, at the discretion of the medical attendant. No infants are received without their mothers. It is interesting to note that the resident physician at the seaside hospital is a lady. The beneficial effects of the trips on the hospital ship has now been amply proved, and especially in the case of infants. In the continued hot weather of the present summer the carrying limit of 1600 has been many times reached. The experiment has been so decided a success in New York that it might be worth a trial in London.

DIPHTHERIA IN PUBLIC ELEMENTARY SCHOOLS.

FOR some years it has been fully recognised that the attendance of children at public elementary schools has been the main factor in the spread of diphtheria epidemics. As Sir Richard Thorne has pointed out in his article on diphtheria in Dr. Clifford Allbutt's "System of Medicine." "in day-schools, and notably in our elementary schools, early attacks of diphtheria have hitherto been apt to be overlooked; and it has not been until the attendance at schools began to diminish by reason of sickness that the matter received attention." No doubt many epidemics have been fostered and intensified in this manner. Even if the disease has been recognised and the school closed the reopening has often led to a recrudescence. In some instances this may have been due to insufficient disinfection of the buildings or to faulty drainage, but provided that every care and skill has been exercised in these matters there in another danger, which has only been comparatively recently recognised—namely, that the specific organism of the disease may exist in the fauces in a state of vitality for several weeks at least after all disappearance of local indications of any throat affection. Therefore when the utmost procurable certainty is required that any one case is no longer infectious, bacteriological examination of scrapings from the fauces is necessary. Acording to the report of Mr. Windle, medical officer for the district of Southall, a rapidly growing urban district of West Middlesex, diphtheria has been present in an endemic form for upwards of two years in that district and he suspected that the public elementary

Digitized by Google

schools were largely responsible for the spread of the disease. The local council and its officers had adopted every means to stay the spread of the malady; the sewerage system had been improved, disinfectants had been freely distributed, the patients had been duly isolated, and every precaution as regards cleanliness and sanitation had been adopted. Mr. Windle, however, pointed out to the board that diphtheria often occurs in so slight a form that its recognition was a matter of difficulty, and thus many cases considered by the parents of the children to be simply "sore-throats" escaped notification and were thus sources of danger to other children. He therefore suggested a very large but excellent scheme—excellent if it could only be carried out everywhere—namely, a full bi-weekly examination of all the children in the board schools. The recommendation was approved and Mr. Windle and Dr. G. B. Macdonald were appointed to carry out the former's suggestion. The method adopted was to examine the tonsils for the pathogenic bacteria, the hands for peeling, the nose and ears for traces of discharge, and the eyes for ophthalmia. In all suspicious cases the children were sent home and when the existence of infectious disease was established the children were taken to the isolation hospital. This experiment is to be tried till the end of the year. We congratulate Mr. Windle on thus acting on the courage of his convictions, and no doubt if such a thorough investigation could everywhere be carried out epidemics of diphtheria would rapidly become things of the past, but we fear the idea is Utopian. In some of the metropolitan districts many thousands of children are attending the schools, cases of diphtheria are constantly occurring as the records of the large general hospitals show, and it would be almost impossible for the medical officers attached to these districts to carry out Mr. Windle's proposal. Much has been done by improved hygienic measures to minimise the spread of diphtheria; the antitoxin treatment has lowered the mortality to an enormous extent, and the prevention of recurrences now lies mainly with the medical officers of hospitals and private practitioners, upon whom it is incumbent to make sure (preferably by bacteriological observations) that the patients' throats no longer harbour the pathogenic bacilli. If this were done as a matter of routine no doubt recrudescences would be far less common than they are at present.

THE ALBUMIN OF HÆMOGLOBIN.

HÆMOGLOBIN contains both colouring matter and albuminous compounds. To the former a considerable amount of attention has been paid, to the latter Dr. F. N. Schulz devotes an article which appears in the *Zeitschrift für Physiologischen Chemie* (Band xxiv., p. 449). Dr. Schulz names the albumin in question globin, and the method he has adopted to obtain it consists in adding a very small quantity of dilute hydrochloric acid to a watery solution of hæmoglobin derived from the blood of the horse. The solution becomes brown but remains clear, and one-fifth of its volume of alcohol is added and the colouring matter taken up by agitation with ether; the watery alcoholic solution is neutralised with ammonia, the precipitate is filtered and washed and again dissolved in water to which a few drops of acetic acid have been added. The superfluous acetic acid is removed by dialysis. The globin thus obtained, which forms about 2 per cent. of the solution, differs in its behaviour from albumin, for, in the first place, by extremely cautious addition of ammonia, it is precipitated, but is redissolved in an excess of the alkali. If the solution has been previously acidified with hydrochloric acid the addition of ammonia still occasions a precipitate, but it is no longer redissolved in an excess. Globin quickly undergoes digestion with pepsin and hydrochloric acid and in the course of four hours is converted into true peptone. When subjected to the action of trypsin it yields leucin but no tyrosin. The percentage composition of globin is C 54·97, H 7·20, N 16·89, S 0·42. The ashes contain oxide of iron, but this must be regarded as an impurity since it is probably derived from the iron of the hæmatin. Inasmuch as the globin is obtained from hæmoglobin through the agency of weak hydrochloric acid it must be regarded as pre-existing perhaps in the form of a salt or ether-like compound. On the breaking up of hæmoglobin a third body is also obtained, which, however, has not yet been isolated. In regard to the chemical nature and status of globin it would appear that in its essential characteristics it resembles histon, for it is precipitated by ammonia from its solution in hydrochloric acid, and the precipitate is insoluble in an excess of ammonia. Like histon it is precipitated by strong nitric acid in the cold, but not when heated, and, like histon, it coagulates on boiling under certain conditions, though it differs from other true products of coagulation in the remarkable facility with which it dissolves in acids. Globin does not, unlike the nucleo-histon of Lilienfeld, inhibit the coagulation of the blood. When injected into a vein it appears in the urine. Dr. Schulz suggests that many cases of albuminuria depend upon the excretion or elimination of globin. The hæmoglobin of the dog gave a globin which in all respects resembles that of the horse; on the other hand, the hæmoglobin of the blood of the goose behaves differently.

EXPERIMENTAL QUININE AMBLYOPIA.

DR. SCHWEINITZ, in an article contributed to the *Ophthalmic Record*,[1] remarks that quinine amblyopia was recognised as long ago as 1829, but that the study of complete cases of quinine amaurosis began in America in 1879, and so many cases have now been reported that from the clinical standpoint quinine blindness is one of the best-studied of the toxic amblyopias. The researches made by himself, by Dr. Brunner, and others in animals and man show that the lesion in quinine blindness is peripheral, that primarily there is an ischæmia of the retinal and optic nerve vessels caused by their intense contraction, and that if the blindness continue for a sufficient length of time atrophy of the optic nerve and optic tract associated with vascular changes indicating vasculitis and endovasculitis ensued, followed ultimately by obliteration of the lumen of the vessels. Dr. Schweinitz, in his experiments upon dogs, found that from the first to the fourth week there was pallor of the discs and great contraction of the vessels during life, whilst examination of the optic nerve with the microscope revealed imperfect differentiation of the fibrous framework and spreading apart of the individual nerve fibrils which were varicose and beginning to be atrophic. At this time there were no changes in the vessels. Later, and about from two to three months after the onset of the blindness, the discs were white and the vessels were almost entirely obliterated when examined with the ophthalmoscope, and under the microscope there was practically complete atrophy of the optic nerve fibres, thickening and collapse of the nutrient arteries of the optic nerve, and occasionally (in two specimens) obstruction of the central vessel of the nerve with a partially organised thrombosis. The atrophy extended throughout the optic nerve, chiasma, and tracts. Dr. Schweinitz proceeds to give a report of a paper by Dr. Ward Holden which was read at a meeting of the American Ophthalmological Society, in which the details are given of the examination of the brain and spinal cord. The optic nerves and eyes of numerous dogs were examined which had been killed at periods ranging from two hours to seven weeks after the first injection of quinine. It was found that as early as the third day after several toxic

doses had been given some ganglion cells presented vacuolation, pallor, absence of chromophilic granules, and breaking down of the cell body, whilst analogous degenerative changes, such as the appearance of large globules of a myelin-like character, were observed in the nerve fibres. The number of cells and fibres so changed continued to increase and on the seventeenth day the first changes in the optic nerve were noticed, consisting in the breaking down of the medullary sheaths in numerous fibres. At about the end of six weeks the ganglion cell and the nerve fibre layers had almost entirely disappeared, leaving large cavities, and the myelin globules were no longer present. Many of the fibres of the optic nerve were broken down and the degeneration of the nerve could be traced up to its fibres in the external geniculate body and pulvinar. The researches of Dr. Holden therefore, whilst supporting the statements made by Dr. Schweinitz, Dr. Brunner and others, appear to demonstrate that in the first instance the effect of toxic doses of quinine is to cause spasm of the vessels, and as a result of the lessened but not obliterated blood-supply the less resistant elements of the inner layers, the ganglion cells, and nerve fibres break down, whilst the cells of the inner nuclear layer are not visibly affected. An ascending degeneration of the optic nerve fibres follows the retinal changes. The microscopical examination of the retina in other forms of toxic amblyopia might probably lead to revelations of a similar character to those in the tissue of the retina so ably described by Dr. Holden.

THE LANE MEDICAL LECTURES.

THE Lane Medical Lectures, founded in connexion with Cooper Medical College, San Francisco, were delivered this year by Dr. T. Clifford Allbutt, Regius Professor of Physic in the University of Cambridge, the subject selected being Diseases of the Heart. It is well known that this important branch of practical medicine is a favourite study with Dr. Allbutt and that he has done much to increase our knowledge of the pathology and treatment of these conditions. In his closing lecture he gave a review of the advancement of medicine during the nineteenth century, a fascinating page of recent history filled with the records of many workers whose labours have effected in almost all departments of medical science and practice such improvements as could not have been imagined a century ago. Dr. Levi Cooper Lane, the President of Cooper Medical College, informs us that Dr. Allbutt's audience were greatly impressed with his power of exposition and with his facility in drawing on his experience for instances to illustrate particular points. As our readers may recollect, the Lane Lectures were delivered in 1897 by Mr. Christopher Heath.

THE BRITISH ASSOCIATION.

THE 1898 meeting of the British Association for the Advancement of Science at Bristol will be remembered as an eventful one. To those who hold that these annual meetings are merely well-organised picnics the result must have been disappointing. The attendance was greater than usual and the interest shown in each of the sections was distinctly in advance of previous years. This can only be accounted for either by reason of the subjects being more than usually attractive or else because the public are acquiring a healthy desire for scientific knowledge. The authorities concerned in organising the meeting are to be warmly congratulated on its success, especially in view of the difficulties involved by the disastrous fire which completely destroyed Colston Hall. In spite of this deplorable occurrence there was not a single hitch in the management of the sections and meeting places. Perhaps the two great features of the meeting which will be most remembered are Sir William Crookes's remarkable Presidential Address and the story of M. De Rougemont's thrilling Robinson Crusoe-like adventures in Australia. There is much contention waging round the latter paper which promises to fill the correspondence columns of our daily newspapers for some time to come. The sectional proceedings practically closed on Monday. On Wednesday, at a meeting of the General Committee, with the President, Sir William Crookes, in the chair, it was decided to hold the next meeting at Dover, and a motion appointing Professor Michael Foster as President-elect was seconded and carried unanimously. A motion was also carried unanimously that the Archbishop of Canterbury, the Marquis of Salisbury, the Mayor of Dover, Lord Herschell, the General commanding the South-eastern district, Mr. Akers Douglas, the Dean of Canterbury, Sir Norman Lockyer, and Professor G. H. Darwin should be asked to accept the position of vice-presidents elect for the Dover meeting.

THE WRECKING OF TRAINS.

THE two recent dastardly attempts to wreck express trains on the Midland Railway, following so closely the remarkable disaster at Wellingborough, cannot be overlooked. The fact of a barrow sliding off the platform at Wellingborough on to the metals and wrecking the Manchester express, going at high speed, with loss of life and severe injuries to passengers, seems to have inspired some miscreant to attempt to bring about a similar awful result. An obstruction was found on the rails shortly after the Wellingborough accident, and close to the same spot, and again on another day a similar obstruction was found on the line at Bedford. A more wicked act than this cannot be conceived, and it is to be hoped that the cowardly and unprincipled perpetrator will be found. It is charitable to think that he is mad, but that does not reduce the necessity of employing every possible means to clap hands upon him. If it should be shown that the act was the deliberate plan of a person enjoying ordinary reason then nothing short of being hanged and quartered should be his lot. After all, it is dangerously simple to place an obstruction upon a railway line and the results may be appalling. Our great trunk lines, over which trains proceed at a great speed, run through dark and deserted places and nothing is easier than for a villainous person to place a "sleeper," "chair," or crowbar on the metals. Cannot something be done in the way of attaching a guard to the engine after the manner of an American "cow-catcher" which would at least prevent the obstruction from getting complicated with the wheels or machinery of the locomotive?

A PATHOLOGICAL PLANTAR REFLEX.

THE *Semaine Médicale*, July 27th, 1898, contains a paper by M. Babinski on a peculiar modification of the plantar reflex termed by him "the phenomenon of the toes," which he first described in 1896. In the normal plantar reflex, besides other movements, flexion of the toes on the metatarsus occurs. In some healthy individuals the toes remain, apparently at least, immobile, but they never execute movements of extension. In certain diseases, on the contrary, a movement of extension, especially of the great toe, takes place. This modification of the plantar reflex M. Babinski terms "the phenomenon of the toes." It may occur in lesser degrees—that is to say, the reflex may be partly physiological, partly pathological; there may be extension of the great toe or of the two first toes and flexion of the others, or stimulation of the external part of the sole may cause extension of the toes and stimulation of the internal part of the sole may cause flexion, or stimulation of any part of the sole may produce sometimes extension, sometimes flexion. This inversion of the normal plantar reflex is found in a

Digitized by Google

variety of diseases: in hemiplegia from any organic disease of the brain (on the paralysed side), in paraplegia, in hemiparaplegia (on the paralysed side), in Friederich's disease, in diffuse meningo-encephalitis, in cerebro-spinal meningitis and in strychnine poisoning, in Jacksonian epilepsy (on the affected side immediately after a crisis). It occurs not only in old cases of hemiplegia with rigidity, but also immediately after the onset of hemiplegia with muscular flaccidity. Similarly in spinal cases it occurs in spastic paralyses from any cause and in recent paralyses from injury of the cord with flaccidity of the muscles and diminution or abolition of the tendon reflexes. On the other hand, the phenomenon was not found in hysteria, uncomplicated tabes, anterior poliomyelitis, or in two cases of section of the spinal cord. M. Babinski points out that the diverse affections in which it is found have this in common: they bring about some perturbation in the pyramidal system, to which he attributes the phenomenon. But it does not imply a grave affection; it may occur in cases of slight and curable paralysis and disappear with the latter. Conversely, the sign may be absent in cases where the pyramidal system is profoundly altered. It may prove valuable in distinguishing organic from hysterical hemiplegia or paraplegia. Also its presence in tabes would show affection of the pyramidal system which otherwise might remain unknown. In the new-born the phenomenon occurs normally. This confirms the theory of its relation to the pyramidal system, for at birth the latter is not developed.

CHLOROFORM FOR DOGS.

IN the *Journal of Comparative Pathology and Therapeutics* for June an article appears from the pen of Professor Hobday which deals with the statistics derived from the use of chloroform in his out-patients' department at the Royal Veterinary College. Out of 500 administrations to dogs one death is recorded, that of "an aged fat pug," and a post-mortem examination revealed a ruptured portal vein. In two instances anxiety was felt; respiration ceased, but the application of artificial respiration and three minims of hydrocyanic acid (Scheele's) were given, the animals recovering. It will be remembered that Professor Hobday, guided by the presumed physiological antagonism between hydrocyanic acid and chloroform upon the respiratory centre, has advocated the employment of this acid as a means for resuscitation in over-dosage with chloroform. As, however, artificial respiration, especially if done when the animal is placed on its side, is usually sufficient to bring a dog round which has been over-dosed, it is difficult to feel sure that the recovery in these cases may not have been due simply to ventilation of the lungs and enforced expulsion of the chloroform vapours. 120 cats were chloroformed by Professor Hobday's method—the aspiration of air over chloroform—and of these 3 died and 1 other was only recovered by restorative measures. In this case hydrocyanic acid (Scheele's), 3 minims, was used with artificial respiration. The deaths among the cats are described and are of interest. A few whiffs of chloroform were given; in the first case the breath was apparently held before anæsthesia was achieved. As the suspension of respiration was thought to be voluntary no resuscitative measures were adopted and too late it was discovered that the cat was dead. There seems little doubt that this was a death due to direct action of too strong a vapour; many such were reported by Snow, who regarded them as arising from cardiac failure. The other deaths were due to respiratory failure the result of gradual over-dosage. The conclusions which Professor Hobday arrives at are: 1. That dogs are good subjects for chloroform when due precautions are taken in its administration and the slapdash method is laid aside for one in which the dose can be properly graduated and the quantity given controlled. Posture and restraint without interference with the movements of respiration are, he considers, of great moment. He advises the "abdominal position" (? prone) with the limbs spread-eagled and hobbled. 2. Cats he regards as much more easily killed by chloroform and requiring the greatest care in their management. Young animals are more susceptible to over-dose than are older ones, the sickly and fat than the strong and well-conditioned.

CONVICTION UNDER THE DENTISTS ACT.

AT the Louth Borough Police-court on Sept. 8th, before the Mayor and other magistrates—including Dr. F. Fawssett and Dr. P. Best—Herbert Manning, 86, Upgate, Louth, was charged for that he, not being a legally qualified medical practitioner, did so use the words "Dental Institute," as to imply that he was registered under the Dentists Act, and also for that he, not being registered under the Dentists Act, 1878, did use an addition—viz., "15 years' experience in modern dentistry," implying he was a person specially qualified to practise dentistry. The defendant was warned about the large board or sign on his premises with the words "Dental Institute," but he did not remove it. He professed to do work at half the price of dentists and to correct their misfits. The Bench inflicted a fine of £7, with 26*s.* costs, or one month's imprisonment. Dr. Best stated that any qualified medical man who coöperated with an unqualified dentist in the administration of anæsthetics is liable to be struck off the Medical Register. The prosecution was conducted by Mr. R. W. Turner, barrister, on behalf of the British Dental Association.

RECOVERY AFTER WOUND OF THE HEART.

AT a meeting of the Società Lancisiana held in Rome on July 9th Dr. G. Parlavecchio described a case of punctured wound of the heart on which he had operated successfully. On the night of July 7th a man, twenty years of age, was stabbed with a knife in the fifth intercostal space on the left side in the parasternal line (the vertical line midway between the border of the sternum and the nipple). He afterwards walked a distance of more than 200 metres (218 yards) to the Hospital of San Giacomo. Five hours later he was found to be suffering from pneumothorax on the left side with extensive effusion of blood into the pleura, the area of cardiac dulness was increased, at the apex the heart sounds were confused, and at the base they seemed to be distant, the pulse was irregular, intermittent, and small. Dr. Parlavecchio suspected a wound of the heart, or at least a wound of the pericardium, but was not able to operate until eight hours after the injury. Chloroform having been given a free incision was made in the fifth intercostal space and much blood escaped on opening the pleura. After resection of the fifth rib a wound admitting two fingers was discovered in the pericardium and was enlarged so as to expose the heart, in which there was near the apex a V-shaped wound, 3½ centimetres (1½ in.) long, penetrating obliquely into the left ventricle and intermittently discharging blood. It was closed with four deeply-applied separate silk sutures, after which there was no further hæmorrhage. The pericardium and the intercostal wound were then sutured, the whole operation lasting 40 minutes. The V-shape of the wound in the heart was probably due to its movement during the infliction of the wound. The patient's survival for the 8 hours preceding the operation may be explained by occlusion of the wound by clot which was displaced during the struggling occasioned by the chloroform. According to the *Supplemento al Policlinico* of August 20th, from which the preceding is taken, the subsequent history of the case was quite uneventful and on August 14th the patient insisted on

Digitized by Google

leaving the hospital. It is added that this is the third case in which suture of a wound of the heart has been followed by recovery.

THE METROPOLITAN ASYLUMS BOARD EXPENDITURE.

IT is satisfactory to see that the Local Government Board has informed the Asylums Board that they have directed their chief inspector, Mr. W. E. Knollys, C.B., to hold after the vacation an inquiry into the causes of the excess of cost over the tenders received for the erection, &c., of the Brook Hospital, the architect's responsibility, and the supervision exercised by the committee and the managers as regards expenditure. We shall look with interest for the report of Mr. Knollys.

THE DROUGHT.

THE drought continues and the outlook in regard to water-supply is serious not only in the East of London but all over the country. It is clear that in the prolonged absence of rainfall our catchment water areas fail to afford an adequate water service and the moral of it is the necessity of adding enormously to the capacity for storage. The community must have an abundant and efficient water-supply at all times since a pure and adequate supply is the first factor in maintaining the public health. The East London Waterworks Company not much more than a year ago very materially increased their undertakings by constructing huge reservoirs near their Tottenham pumping station and they possess further powers we believe for adding again to the storage capacity. In spite of this the water-supply has failed, a fact practically admitted by the company, the admission amounting to an acknowledgment that the sources of supply, the Lee and the wells in its neighbourhood, are unequal to the increasing demand. When the enormous growth of London "over the border" is considered—the area supplied by the company—some idea of this increasing demand may be realised. We have no wish to inspire alarm, but if the present abnormally steady condition of meteorological things continues the consequences may be of the most serious kind. The rivers are depleted to the utmost, the drains are not adequately flushed, and there is little flow in the upper reaches to carry off the daily discharge of the sewage outfalls. There must be something anomalous in the fact that the first necessity of life is also employed to carry away from sight human excreta. According to the present system we draw on the river for a supply of drinking water purified with care by an elaborate scheme of filtration and then use the purified water as a means of conveying sewage back again to the same river. Thus the water in the river is withdrawn in a comparatively pure state and returned foul. With a population increasing at an almost alarming rate this state of things cannot go on much longer without disaster. If the water carriage system is to be continued the supply for drinking purposes and the supply for flushing purposes must be, we think, perfectly distinct unless a fresh and more abundant source be obtained. In this perhaps we have the most powerful argument for seeking new sources of supply. Thus, could the Welsh scheme be realised the maximum flow of the Thames and Lee would not be affected—there would be no depletion; on the contrary, the volume of the rivers would be materially augmented, the water would always be clean, and in abnormal times of drought the water catchment area of the Welsh mountains and valleys would in a way maintain the normal amount of water in these rivers. The recent records of rainfall are of interest. We are indebted to Mr. Glaisher, F.R.S., for the following figures: London average, 0·90 in.; Wales, 4·74 in. Further, there would be no need for sinking wells, which in the neighbourhood of rivers draw seriously on the flow. There is no difficulty in increasing if need be the capacity of Nature's own great storage reservoirs, as is instanced in the case of Loch Katrine, and in Wales the simplest possible engineering scheme can be turned to account in conserving colossal tanks of water in the valleys of that country on a scale quite comparable with the Scottish lakes. A member of our staff recently visited Loch Katrine and gained some interesting particulars connected with this remarkable water-supply. It has been found necessary to increase the capacity of the loch owing to the greater demands of an ever-growing population. A new tunnel of twice the calibre of the one built now nearly forty years ago is in course of construction. At present some 49,000,000 gallons of water per diem are discharged through the old tunnel, while 5,000,000 gallons are allowed as compensation to flow over the sluices at the Trossachs end of the loch so as not to spoil the flow of the river Teith. The inlet of the tunnels is about 7ft. below the surface of the water. In view of increasing requirements the sluices are being enlarged and raised, which will bring the level of the water so many inches higher as to increase the capacity by billions of gallons, the loch being 8 miles long, and thus will meet the increased withdrawal of water by the new tunnel to Glasgow. The supply has been found to be pure, ample, and abundant for now nearly forty years without seriously affecting the volume of water or flow of the river Teith. Moreover, the water is remarkably pure and soft and strict surveillance is adopted to prevent any possible contamination. The drought has, however, affected even this great natural reservoir. We learn that the water-level has not been so low for seventeen years, the depreciation amounting to 10 in. The slightest fall of rain, however, soon restores this difference. At a time when one of the worst water famines has occurred in the history of metropolitan affairs these particulars are not without interest and instruction. As far back as forty years ago Glasgow was alive to the necessity of providing an adequate and pure supply of water. The source adopted has not only not failed, but by a simple engineering plan it may obviously be greatly increased, and there is little limit toward extending this supply in accordance with future needs. It is a similar source of supply to which, in view of present conditions, London must turn, although it must be owned that London is not so favourably situated as Glasgow in this respect. There is, however, a wonderful and inexhaustible watershed in Wales which, were it to be tapped for London's needs, would require a waterway of over 100 miles in length, but this would offer no difficulty from the engineering point of view, whilst the adoption of the scheme would solve a great sanitary problem.

THE FREQUENCY OF VOLVULUS OF THE SMALL INTESTINE.

VOLVULUS of the small intestine is generally supposed to be rare; few cases are seen either at operations or necropsies. In the *Medical Chronicle* of June, 1898, Mr. Thorburn has published some cases which tend to show that this form of intestinal obstruction is not as uncommon as is supposed and that spontaneous reduction may take place, so that neither operation nor necropsy reveals the cause of obstruction. Mr. Treves has already adopted this hypothesis as an explanation of certain cases of acute intestinal obstruction, occasionally recurrent, which recover without surgical treatment, but neither he nor others has observed the condition. Three cases are narrated. Laparotomy was performed in a case of acute intestinal obstruction; a coil of small intestine was found rotated on its mesentery. It was readily thrown back into the normal position; in fact, it fell back as soon

Digitized by Google

as it was handled. At the two ends of the coil, where the intestine crossed itself, the wall was pale and the lumen was contracted. These parts recovered their normal appearance under the eyes of the operator. A man suffered for five days from complete obstruction of sudden onset. Within a few minutes of palpation of the abdomen, while the question of operation was being discussed, the bowels were suddenly and freely moved. But the patient's prostration increased and he died in six hours. A sharply defined segment of the ileum, 6 in. in length, black and gangrenous, was found. In the third case at a laparotomy Mr. Thorburn found about 18 in. of small intestine similarly affected. In the second and third cases there is no direct evidence of volvulus, but there is no other explanation of the gangrene, for there was no hernia, old-standing peritonitis, bands, or interference with the mesenteric circulation. In the Transactions of the North of England Gynæcological Society, 1895, Dr. Donald has published a case of sharply defined gangrene of 5 ft. of ileum, which caused death thirty-five hours after ovariotomy and has adopted this explanation of a spontaneously reduced volvulus. Mr. Thorburn says that no new principles of treatment can be deduced from these cases.

ALPINE ACCIDENTS.

THE holiday season as usual is producing its annual crop of accidents. In many instances, notably those disasters which occur to persons when bathing or boating, the fault is generally their own and is due to ignorance. But we cannot always say this, for the two lamentable accidents which have lately happened in the Alps show that even when care and forethought are taken "the iced mountain top" still has its perils. All the world is the poorer for the loss of Dr. Hopkinson, the well-known electrician, and the circumstances of his death are rendered all the more sad by the loss at the same time of his three children. The peak which Dr. Hopkinson ascended, namely the Petite Dent de Veisivi, is not considered dangerous, and Dr. Hopkinson was an expert mountaineer. But he was heavily handicapped by the presence of two young and untried climbers. How the fatality happened will never be known, suffice it to say that it did happen. The other accident is notable for one of the most magnificent pieces of heroism which we can recall to mind. Professor Nasse, well known in Berlin as the assistant to Professor von Bergmann, and Dr. Borchardt, with two guides, the four roped together, were crossing the Piz Balne over a snow bridge which was considered quite safe by the guides. The bridge gave way and the leading guide and Professor Nasse fell into the crevasse. Professor Nasse had the rope round his chest and hung in mid-air for half an hour. To relieve the intolerable strain the leading guide cut the rope between himself and Professor Nasse and disappeared into the depths. The other guide and Dr. Borchardt were then able to pull Professor Nasse up, but he was dead. It is cheering to know that the guide who had so willingly offered his own life was not killed but was found unhurt by a rescue party. But as an heroic action it is beyond all praise. Men have risked their lives on the battlefield in many very noble ways, but there they have the excitement and the lust of fighting to keep them up. Here, however, there was nothing of the kind, almost certain and horrible death stared him in the face. Two actions we can recall which are in some way comparable—the one which happened in England the other day when the driver and fireman of the Great Western express stuck to their engine, so as to stop the train, although being boiled alive, and the other the well-known instance of the steersman on the burning steamer on Lake Erie who stood at the wheel while slowly scorching so that he might steer the ship safe to land. Such deeds are beyond all praise, and let us not forget them.

THE OPENING OF LABORATORIES OF PHYSIOLOGY AND PATHOLOGY AT LIVERPOOL.

AMONG those who have accepted invitations to be present on Oct. 8th at the opening, by the President of the Royal Society, Lord Lister, of the new laboratories of Physiology and Pathology given by the Rev. Mr. Thompson-Yates to University College, Liverpool, are the following: the Duke of Devonshire, Lord Derby, Lord Spencer, Lord Ripon, Lord Kelvin, Professor Michael Foster, Professor Virchow, Mr. A. J. Balfour, Sir Douglas Galton, Sir Samuel Wilks, Sir Richard Thorne, the Bishop of Chester, the Bishop of Carlisle, the Bishop of Ripon, Sir William Gairdner, Mr. Justice Kennedy, Sir James Crichton Browne, Sir Archibald Geikie, Captain Abney, C.B., Sir George King, Professor Ramsey, Professor David Ferrier, Professor Rücker, Dr. Pavy, Mr. R. B. Haldane, Sir John Batty Tuke, Sir Henry Littlejohn, Mr. Thistleton Dyer, Professor Darwin, Professor Schäfer, Professor Kanthack, Professor Burdon-Sanderson, Professor Halliburton, Professor Meldola, the Dean of Lichfield, Professor Charlton Bastian, the Hon. Sydney Holland, Professor Rose Bradford, Professor Forsyth, Professor Bower, Dr. Alexander Cope, Professor Crookshank, Dr. Lauder Brunton, Professor Waller, Professor Noel Paton, Dr. Ludwig Mond, Dr. Mott, Professor Poulton, Professor Stirling, Professor Liveing, Mr. Gerald Yeo, Professor Macallum, Dr. Byrom Bramwell, and many others well known within and outside the profession. The ceremony will commence with the conferment of the honorary degree of Doctor of Sciences upon Lord Lister at the hands of the Chancellor, Earl Spencer. Lord Lister will then, with the President, Earl Derby, proceed to open the new laboratories. In the evening a banquet will be given by the Lord Mayor in the City Hall.

THE BACILLUS OF RABIES.

THERE are many diseases the communicability, incubation, and general phenomena of which compel us to regard them as bacterial, even though the microbes should for ever elude observation. Such a disease is rabies. Pasteur to the last contented himself with the empirical procedure of attenuating the virus of a hypothetical microbe, and so long as the results he aimed at were satisfactory he worked at improving his methods, leaving the more purely scientific aspect of the question to bacteriologists in the future. Accordingly Foll, Rivolta, Ferran, and Spinelli have claimed to have detected in certain secretions and preparations a bacillus the specific character of which was made highly probable by Sanfelice, who, employing a special staining process, demonstrated its presence in large numbers in the spinal cord of a boy who had died from hydrophobia. Memmo of Rome confirmed the observation of Sanfelice and proved the virulent character of the micro-organism, which he described as a blastomycete and the presence of which he detected in several cases of rabies, but quite recently he has succeeded in cultivating it in artificial media and in reproducing by inoculations with these cultures the disease with its distinctive characters in dogs, rodents, and birds respectively. These experiments and observations, which, fulfilling the most stringent demands of bacteriological criticism, leave no room for doubt, are described in the *Centralblatt für Bakteriologie*, Abtheilung I., Band xxi., 17, 18. He found the microbe in the cerebro-spinal fluid and the substance of the brain and spinal cord, in the saliva and parotid gland, and in the aqueous humour of four dogs dying from the natural disease, and of rabbits, guinea-pigs, and pigeons in which it had been produced by inoculation. It grew better in

Digitized by Google

fluid than in solid media, the best being bouillon with glucose slightly acidulated with tartaric acid. The growth did not become manifest under a week and was easily arrested by "air infection," as through the access of dust from the laboratory. Inoculated with cultures of the fourth generation, purified by successive plate cultures, guinea-pigs and rabbits developed symptoms of paralysis of the hind limbs, &c., after from 11 to 20 days and died from the paralytic form of the disease. With dogs the inoculation was prolonged to from 30 to 60 days, when they were attacked with all the symptoms of typical natural rabies. Though Memmo does not suggest the application of his discovery to the prophylaxis of hydrophobia, it is not impossible that artificial cultures may be found capable of definite attenuation so as ultimately to simplify the methods adopted by Pasteur.

THE TREATMENT OF CHRONIC CERVICAL LYMPHADENITIS BY THE INTRODUCTION OF DRUGS INTO THE CRYPTS OF THE TONSILS.

IN the *Boston Medical and Surgical Journal* of May 19th. 1898, Dr. J. L. Goodale has described this novel and ingenious method. His observations refer to the glands at the angle of the jaw and not to the occipital, jugular, and submental glands. The difference between the stout, compact epithelium covering the exposed surface of the tonsil and the delicate loose structure lining the crypts leads him to suppose that absorption takes place chiefly through the latter. A number of foreign substances were introduced into the crypts of tonsils destined for excision and the tonsils were removed at varying intervals and examined microscopically. The substances were found to have been absorbed and to have passed into the interfollicular lymph channels. To exclude complicating influences in the cases selected for treatment adenoid hypertrophy was absent and the lymphadenitis was out of proportion to discoverable disease of the tonsil, particularly hypertrophy. In most cases a 10 per cent. aqueous solution of iodine was used. Three or four drops were drawn into a syringe through a canula, which was introduced into a crypt as far as it would go and the fluid was expelled. The injections were repeated every third or fourth day. In most cases a remarkable reduction in the glandular swelling took place. For example, a pale, poorly nourished girl, aged eight years, had a gland at the right angle of the jaw measuring 2 in. by 1 in. The gland became steadily reduced in size and in eight weeks measured ¾ in. by ½ in. In a few cases apparently suitable for this treatment no improvement resulted; possibly there was some source of infection other than the tonsils.

INSANITARY AREAS AND THE DRINK QUESTION IN LIVERPOOL.

OUR readers will remember that in a recent notice of the report for 1897 of the medical officer of health of Liverpool we directed attention to his anxiety about the continued operation of intemperance in Liverpool as a cause of death, not only direct but insidious and far reaching. "Deaths attributed to excessive indulgence in drink had been more numerous than from scarlet fever or from all the other forms of fever—viz., typhus, typhoid, and simple continued fever—combined." The indirect operation of this vice was equally clear. "Proof," he said, "is clear that the poverty and the sickness and the mortality which owe their cause to excessive indulgence in drink are not fully indicated by inquests." He adds: "It will be noted that two of the areas of excessive disease and mortality dealt with by the Insanitary Property Committee (p. 142) are over-supplied with public-houses." It is not surprising that the anxiety of the medical officer of health has extended to the magistrates and that they have determined to face this problem and the means of solving it. They had objected this year to the renewal of licences in areas dealt with by the Insanitary Property Committee, and they feel that they are warranted in this course. But they have resolved to give twelve months' notice in order that both the licensees and the public shall have time to think out the question. They intimate that at the end of this period they will deal with the question of over-supply from whatever cause in every part of the city. The bench are satisfied that the houses are largely in excess of reasonable requirements and hope that the trade will take the same view. In this action the Bench will have the support of public opinion and certainly of medical opinion, which recognises in excessive drinking a most powerful factor in the destruction alike of property and of health. It may be hoped that before the lapse of a year the magistrates of the country may have the advantage of the Report of the Royal Commission on this question, which will impose a great responsibility on Her Majesty's Government. The number of public-houses is only one element in this great question, but it is an important one. Apart, as we understand, from this general resolution of the Liverpool Bench, the justices at the recent Licensing Sessions have withheld 26 licences—that is, 21 from full public-houses and 5 from beershops.

THE PREVENTION AND TREATMENT OF PULMONARY PHTHISIS.

THE movement for the repression of tuberculosis initiated at a meeting at Sir W. Broadbent's house[1] has advanced a stage further in the North of England than in the metropolis. It has been there recognised that public instruction in the principles and methods of preventive medicine as applied to tuberculous disease may form a powerful means of checking the spread of pulmonary phthisis. A society for this purpose, consisting of medical and lay members, has been formed as the outcome of a resolution passed at the annual meeting of the North of England Branch of the British Medical Association, held in the Town Hall, Sunderland, on July 11th. Although its title of "Society for the Prevention and Cure of Consumption in the County of Durham" indicates a merely local organisation the example is one which deserves to be followed everywhere and the result of such operations on a large scale would inevitably be an immediate reduction in the death-rate from this cause. The objects of the society are (1) to teach the public that consumption is an infectious disease, to show how its spread may be prevented, and to call attention to the fact that it is curable in the earlier stages in a large proportion of cases when systematically treated by the open-air method; (2) to urge upon sanitary authorities in the county the necessity of taking steps to stop its ravages and of obtaining further powers for so doing; and (3) to provide a properly-equipped open-air sanatorium for the treatment of suitable cases, admission to which will be free to the poor, but all patients who can contribute towards their maintenance ought to do so, in order that the institution may be largely self-supporting when once fully started. A meeting will be held on Sept. 20th, in the town-hall, Sunderland, for the purpose of appointing a central committee, with auxiliary committees throughout the county, to carry out the above objects. The prospectus of the society states that there are in this country 250,000 persons affected with phthisis, and that 60,000 die yearly from it. In the county of Durham, with a population of 1,128,000, the total number of deaths in 1897 was 19,464, of which 1450 were due to phthisis and 954 to other tuberculous diseases. It is also pointed out that there is in England no public provision for the rational open-air method of treatment, whilst in German open-air sanatoria, in places which have nothing special in the way of climate,

about 34 per cent. of recoveries are reported. The office of the society is at No. 43, West Sunniside, Sunderland.

LUNACY IN THE COLONY OF VICTORIA.

THE annual report of Mr. J. V. McCreery, inspector of lunatic asylums, shows that the total number of registered lunatics in the colony of Victoria on Dec. 31st, 1897, was 4346 (2296 males and 2050 females), of whom 4341 were on the books of the seven public asylums, the largest of which is that at Kew, containing 1021 inmates. The persons admitted during the year 1897 numbered 771, the highest admission rate recorded since the opening of the asylums and an increase of 88 as compared with the previous year. The proportion of the insane to the sane population was 1 to every 271. The recoveries were 217, against 210 discharged during the preceding year. The percentage of recoveries on admissions was 27·96 and of relieved 11·08. The number of patients who died during the year was 324, the percentage of deaths on the daily average numbers resident being 7·93. 3 patients committed suicide, 1 died through being knocked down by another patient, and 1 who assisted in cleaning lamps injected kerosene into his body and died from the results of the inflammation so caused. The general health of the asylums was good, and with the exception of a few cases of scarlet fever at the Idiot Asylum the institutions were free from contagious disease. On Jan. 1st, 1897, there were 198 patients on probation with their friends, and during the year 324 in addition were allowed out of the asylums. The system of allowing patients out on trial has been growing more and more into favour in the Victorian asylums, where it is used to a greater extent than in any other part of the world. It is considered that to allow the patient to mix in the world for a reasonable time away from the asylum restraint is a good test of mental recovery. The weekly cost of maintenance was 8*s.* 6*d.* per patient. The medical service seems not to be popular. At the date of the report there were two vacancies for junior medical officers but no applicants.

QUANTITATIVE ESTIMATION OF SUGAR IN URINE.

IN the *Deutsche Medicinische Wochenschrift* of Sept. 1st Dr. Richard Benjamin of the University Klinik in Berlin strongly recommends K. B. Lehmann's new iodine method of estimating urinary sugar on the grounds both of its precision and its convenience for medical men. It is based upon De Haën's volumetric estimation of copper by means of iodine. A definite quantity of Fehling's solution, the amount of copper in which is exactly known, is brought to the boil, treated with a measured quantity of the saccharine solution, kept boiling for some minutes, and passed through a very small filter. The filtrate and washings are made up to 250 c.c., of which 50 c.c. are treated with iodide of potassium and acidulated with sulphuric acid. The free iodine is then estimated with decinormal hyposulphite of sodium in the usual way. Dr. Benjamin says that 60 c.c. of Fehling's solution and 25 c.c. of a half per cent. or 1 per cent. saccharine solution may be used, but in some of his published experiments he took 30 c.c. of copper solution and 5 c.c. of diabetic urine. In addition to this estimation of the residual copper in solution a useful alternative method, especially when the amount of sugar is small, is to dissolve the cuprous oxide on the filter cautiously in nitric acid and estimate it volumetrically. As the nitrous acid produced by dissolving cuprous oxide in nitric acid would liberate iodine, it must be destroyed by warming with a little urea. Dr. Benjamin tested the process in a variety of ways, using saccharine solutions of known strength and also diabetic urine, both in the natural condition and diluted with an equal quantity of water and with the addition of known amounts of glucose. In all cases the results agreed very well. He found that 315 parts of copper correspond to 165·3 parts of sugar. There is a description of the process by Lehmann in vol. xxx. of the *Archiv für Hygiene* and one by E. Riegler in Part I. of the *Zeitschrift für Analytische Chemie* for 1898.

HISTOLOGY OF MUSCLE—NEURO-MUSCULAR SPINDLES.

DURING the last few years much attention has been paid to peculiar structures brought into relief by modern methods of histology to which Signor Ruffini has applied the term neuro-muscular spindles; the results of his researches are given in the July number of the *Journal of Physiology*. These structures are found scattered through the muscle but are especially numerous and closely set, as Sherrington has shown, near the tendon and in the proximity of aponeuroses and intra-muscular septa. They vary in length from about $\frac{1}{4}$ to $\frac{1}{8}$ of an inch and are about $\frac{1}{12\frac{1}{5}}$th of an inch in diameter. Kölliker counted fifteen in each belly of the omohyoid of a child of four. It is remarkable, however, that they appear to be absent in the ocular muscles. Each spindle presents a certain resemblance, noticed by Ranvier, to a Pacinian body since it is enveloped in a capsule or sheath composed of concentric lamellæ of dense fibrillated connective tissue covered on each surface with a layer of endothelium and separated by a layer of lymph. The sheath is surrounded by the perimysium internum which divides it from the surrounding muscular fibres. The centre of the neuro-muscular spindle is occupied by a small fasciculus of striped muscular fibres which has been designated "Weissmann's bundle" after its discoverer. These muscular fibres are from two to twelve in number in different animals and are smaller than the ordinary fibres of the muscles, which led Hassall to regard them as subservient to the production of neuro-muscular fibres. One end of the "Weissmann bundle" is muscular, the other is tendinous. In the muscular or proximal end lie the so-called parent muscular fibres which by longitudinal division make daughter fibres. The chief interest of these neuro-muscular spindles lies in their relation to the nerves. Every neuro-muscular spindle in the cat receives a nerve fibre which just before joining the spindle almost always splits into two or more secondary divisions, which do not separate but course together and plunge into one and the same spindle. Each of these secondary divisions in turn subdivides into tertiary branches in close proximity to the Weissmann bundle, and becoming flattened and losing their myelin sheaths, end on one of the muscular fibres. There are three modes of termination. The primary ending is constituted by the nerve fibre running spirally round the muscle fibre and terminating in a free and dilated extremity, or in some instances by running for some distance straight upon the fibre, but giving off at intervals riband-like fibres which encircle the muscle fibres. In the secondary ending the branches of the nerve fibre quickly break up into a large number of varicose axis-cylinders joined together by extremely delicate and short filaments, the whole resembling a spray of flowers. In the third node or plate ending the non-myelinated nerve fibre breaks up at the preterminal node into a few short, extremely delicate, branched endings. These quickly begin to form what may be called coronets by means of rounded varicose nerve fibrils and very minute hooks set side by side. These coronets, which unite in various ways in the plate, terminate in free and enlarged ends. Signor Ruffini is unable to state definitely the function of the spindles or whether the nerves are sensory. He has satisfied himself that the plate endings have not a motor function. The original article is illustrated by some excellent drawings of the appearances see

THE OFFICIAL REPORT ON THE EPIDEMIC OF TYPHOID FEVER IN MAIDSTONE IN 1897.

IN this report three inspectors, Mr. J. S. Davy, Dr. Theodore Thomson, and Mr. Willcocks, of the Poor-law, Medical, and Engineering Departments of the Local Government Board respectively, give an account of the evidence as to the epidemic of typhoid fever given before them at a public inquiry held at Maidstone in January last and extending over eight sittings. The report with appendices makes a considerable volume of 84 pages of folio, and is illustrated by maps, diagrams, and photographs. Although it gives a clear account of the epidemic and the inspectors sum up their subject concisely and judicially, yet we must confess that we find in the report no indication of the advantage of the Local Government Board's new policy of investigating an outbreak by means of a formal public inquiry. If the purpose of the new departure was to satisfy local opinion it is quite certain that the report has appeared too late to attain its object. From a scientific standpoint the proceeding is a misfortune. Having in mind the knowledge gained in the past from the admirable investigations of epidemics made by Dr. Thomson in the ordinary course of the work of the Medical Department of the Local Government Board it seems a pity to find that at Maidstone his services were mainly utilised in hearing other people's evidence some three months after the event.

The population of the borough of Maidstone was estimated at 33,830 in 1897. The incidence of typhoid fever was as follows:—

Totals	1786	1711	107	107	45

The Maidstone Water Company supplied the borough from springs in three distinct gathering grounds by way of three distinct systems of mains. The incidence of the fever upon these three water areas was as follows:—

—	Houses.			Persons.		
	Supplied.	Attacked.	Per cent.	Population.	Attacked.	Per cent.
Cossington supply ...	671	19	2·8	3,355	29	0·86
Boarley supply ...	1,410	63	4·46	7,050	69	0·97
Farleigh supply ...	3,916	1,077	27·5	19,580	1,583	8·08

The altogether excessive incidence upon persons consuming Farleigh water was made more significant by various facts recorded in the report. The County Asylum, which received Farleigh water, sustained 107 attacks. In the barracks, with a population of 300, supplied from the Boarley service, and in the prison with an average population of 171 supplied both by a private well and from Boarley, not a single case of typhoid fever or diarrhœa occurred. In the rural parishes of East Farleigh and Barming, containing together a population of about 2300, a total of only 68 houses were supplied by Farleigh water. The inhabitants of these 64 houses sustained 34 attacks; in the rest of the parishes only 2 cases (as to which there were no particulars) occurred. Many other facts of this kind recorded by the inspectors put the relationship between the epidemic and Farleigh water beyond doubt. While, however, the inspectors conclude that polluted Farleigh water was the essential cause of the outbreak, and that infection from polluted soil and defective water-closets and drains played only a subordinate part in the earlier and acuter stage of the epidemic, they record their opinion that "many of the cases in the borough were due to defects of drainage and sewage, with consequent pollution of the soil of the town." These defects, as was pointed out last year by the Special Commissioner of THE LANCET, were everywhere conspicuous. In particular we learn that nearly one-half of the water-closets of the place were without mechanical means of flushing, and that a large number of the sewers were objectionable brick barrel drains. Conditions such as these probably had much concern with the considerable number of typhoid fever cases which occurred after the Farleigh water-supply had been cut off.

The Farleigh supply was derived from a series of springs in the Kentish ragstone (of the Lower Greensand series). Certain of these springs, particularly the Tutsham in Orchard, Tutsham in the Fields, and the South-eastern springs were undoubtedly fed from superficial sources, while their gathering grounds were hop and fruit gardens, heavily manured, on which great numbers of persons are employed at certain seasons of the year. Evidence was received that shortly before the epidemic the neighbourhood of some of these springs was "plentifully covered with human excrement." One of the most interesting points in this report is a diagram prepared by Mr. M. A. Adams, which suggests the manner in which after a period of drought had established cracks in the soil a sudden rainfall would have washed these surface pollutions directly to the springs. Mr. Adams also pointed out a probable relationship between meteorological conditions, rise of subsoil water in the neighbourhood of the springs, and the onset of the epidemic, and put forward some interesting views upon certain attacks of diarrhœa which had immediately preceded the outbreak. Although stating their reasons for believing that many of the springs were subject to serious risk of pollution, the inspectors state that they have no evidence to show either how the specific pollution was introduced into the supply or which of the springs was thus polluted.

Much chemical and bacteriological evidence was given at the inquiry, almost all of which tended to cast serious suspicion on the Farleigh service. It was hardly to be expected that typhoid bacilli should have been found in the Farleigh water, nor was this the case. But in certain of the springs Dr. Washbourn in September and Dr. H. E. Durham in October found typical as well as atypical bacillus coli. Dr. Sims Woodhead, called in to advise the company at a later date, found no bacillus coli which he considered typical, but he obtained colonies which he thought might be indicative of "surface relations." As the inspectors point out, the "relations" between water-supplies and the "surface" of gardens or fields like those which surround the Farleigh sources must be extremely dangerous.

Space does not permit us to dwell upon other matters in this report. The measures adopted in repression of the outbreak appear to have been thorough, although undesirable delay seems to have occurred before the water company shut off the whole of the suspected Farleigh supply. The borough hospital and temporary hospitals were freely used, 381 cases being treated. For work in the hospitals and in the town an extra staff of medical officers and 139 trained nurses were engaged and much voluntary assistance was given. An excellent organisation for washing infected linen was established, some 3600 articles being washed each week. Sewers were flushed, and the Farleigh mains were washed

Digitized by Google

out with chloride of lime solution. £27,888 were subscribed to the relief fund, including £4000 from the Lord Mayor of London's Fund. Poor-law relief was granted to the extent of nearly £1500. The execution of these emergency arrangements appears to have merited all praise. The inspectors conclude their report by expressing doubt as to whether "the regulations of the Board relating to the duties of medical officers of health and the statutes which regulate the powers and obligations of private water companies are sufficient to ensure a reasonable amount of protection to the public health."

BULUWAYO HOSPITAL.

THE medical and surgical statistics of Buluwayo Hospital for the twelve months ending June 30th, compiled by Dr. Frank Arnold, the resident surgeon, give much valuable information as to the health conditions of this part of South Africa. The total admissions during the twelve months were 1619, of whom 1204 were Europeans and 415 were natives. There were 119 deaths, 48 among the Europeans and 71 among the natives. The summary of admissions of Europeans is as follows: Malarial fever (including 8 cases of blackwater fever), 701 cases with 19 deaths; dysentery, 71 cases with 11 deaths; typhoid fever, 23 cases with 4 deaths; other diseases, 359 cases (arranged under 71 headings) with 12 deaths; poisoning, 2 cases, neither of them fatal; accidents, 48 cases with two deaths. The deaths of Europeans were due to the following causes: Malarial fever, 19; dysentery, 11; typhoid fever, 4; pneumonia, 3; heart disease, 3; Bright's disease, 1; alcoholism, 2; gunshot wound, 1; shock of injury, 1; phthisis, 1. There were 22 operations performed upon Europeans under anæsthetics (chloroform or A.C.E. mixture) without any fatal result. There were 4 post-mortem examinations. The summary of admissions of natives is as follows: Malarial fever, 133 cases with 17 deaths; dysentery, 45 cases with 19 deaths; other diseases (arranged under 41 headings), 155 cases with 32 deaths; accidents, 78 cases with 2 deaths; poisoning, 4 cases with 1 death. There were 19 post-mortem examinations. The deaths of natives were due to the following causes: Dysentery, 19; malarial fever, 17; tuberculosis, 7; pneumonia, 11; other diseases, as specified, 17. The subjoined table shows the monthly admissions for malaria, together with meteorological data supplied by the Rev. Father Barthelemy, S.J.:—

Month.	Malaria admissions.			Temperature (Fah.).		No. of rainy days.	Rain (inches).	Mean barometer (inches).	Relative humidity (per cent.).

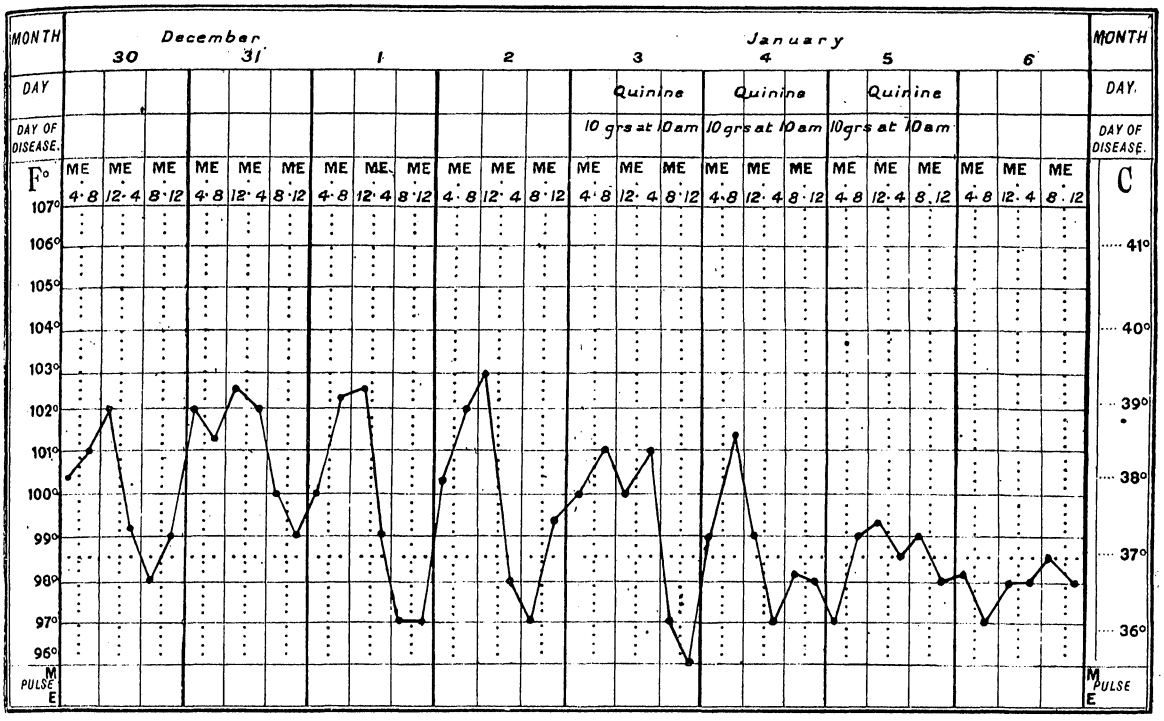
We are indebted to Dr. Arnold for the following notes accompanying the statistics.

1. EUROPEANS.

The hospital serves as the centre for a very large area; by rail, waggon, and patrols of the British South African Police sick people are brought in from distant parts. The past "wet season" is reported to have been an unusually unhealthy one.

"Blackwater fever" is so called on account of the dark colour of the urine. Cases admitted here have generally come from districts known to be rife with malaria. Sometimes they have been unconscious on admission, vomiting coffee-ground-coloured remnants of food, and have died in 48 hours; at other times they come in in a state of profound anæmia with a yellowish tint of skin and conjunctivæ and temperature subnormal, urine of dark colour but giving negative results on testing for blood or bile. In a few days the temperature rises, perhaps to 103° or 104° F., vomiting of bile (green) is profuse, and the urine becomes tea-coloured and sometimes port-wine-looking; pain in the epigastrium and intense headache are complained of; the bowels are usually confined and difficult to move. As the temperature falls the urine clears and the general condition improves. Albumin may sometimes be found in the urine during the paroxysm. Generally blood can be demonstrated in the urine, either actual blood discs disorganised or hæmoglobin, but sometimes neither by microscope nor chemically can such be proved; there is simply the tea colour. In the intervals between the paroxysms the patient is sometimes markedly jaundiced and bile pigment and salts can be found in the urine. Quinine appears to be quite useless and it seems best to deal with symptoms as they arise. With proper accommodation, &c., together with some of my routine work taken by a junior—to be appointed—I hope to be able to study this variety closely the next wet season.



The antipyretics, antipyrine, antifebrin, and phenacetin, especially the last named, are of great use here in reducing high temperatures in malarial fever. Whatever may in theory be the pharmacology of these drugs in malarial fever they act rapidly, producing free perspiration and affording immediate relief of headache, &c. Where perspiration does not follow their exhibition the fall of temperature is not marked, but the distress of the patient is nevertheless relieved. It is generally supposed that the lowering of the temperature is of central action, hence this sweating is of interest.

Typhoid fever is not prevalent to any extent; the type of the past year has been markedly asthenic. Two patients died within 3 days from perforation and general peritonitis; 2 more had intestinal hæmorrhage—1 severely. Turpentine in 60-minim doses appeared to check it. The temperature charts of typhoid fever cases show peculiar rises and abnormal falls. At times a periodicity can be traced in these thermometric excursions. Enclosed is a chart showing a maximum rise at 12 noon each day, when normally the curve as a whole should be descending. The influence of quinine is well shown. The mistura chlori of Burney Yeo ("Medical Treatment") has been given largely by me. Cases seemed to do well with it. The chlorine can as described be detected in the evacuations. I have seen no cases that could be called typho-malaria, although malaria modified the temperature charts of practically every typhoid fever case and, indeed, most other charts. It is to be expected in a malarious country that the residents should show signs of the endemic disease and that these signs should be apparent whether they are suffering from another acute disorder or not.

Two deaths from acute pneumonia occurred in men admitted in an advanced stage of the disease, and a third in a chronic drunkard. All the cases of phthisis were imported and not contracted here. Only early cases of phthisis are likely to stand this climate. Except in the middle of the dry season there are factors in the climate which would be harmful to advanced cases. The dry season is ushered in in May with cold winds and at intervals fine-dust storms—these soon give way to three or four months of continuous fine dry weather, cold at night, hot in the day, with a considerable mean range of temperature. Towards the end of the dry season the heat becomes more marked, thunderstorms and magnificent displays of lightning are common, and about November deluges of rain suddenly close the dry season and mark the onset of the wet season. During this wet season the advanced phthisical subject in common with the healthy runs the risk of malaria which if contracted will handicap him in struggling against his chronic disorder. Also, the standard of personal and domestic comfort, although good and improving, is not equal to the European, this is an important item often overlooked by those who send phthisical sufferers from home.

In connexion with the two successful cases of abscess o

Digitized by Google

Four-hour chart showing malarial rises of temperature at 12 noon and the effect of quinine upon these rises.

the liver no harm resulted from exploratory aspiration—indeed, without such a proceeding the cases could not have been diagnosed. The exploring syringe was also used in two other instances without harm, although negatively. One interesting case of old injury to the skull was admitted. A European woman was struck on the forehead by a bottle. Two months later she was admitted. The sinus was 1 in. above the centre of the left orbital ridge, there was complete aphasia and right spastic hemiplegia. The temperature was 100°. I suspected frontal abscess and trephined over the sinus. The ring so removed had a hole in it and the inner table was carious. Exploration of the frontal lobe in five different directions to a depth of about 2 in. yielded nothing. The wound healed almost by first intention, the temperature fell and kept down, potassium iodide was exhibited, and complete recovery of speech and movements ensued.

In regard to the deaths, 2 were directly and 6 indirectly due to alcoholism, although the latter were admitted for other reasons.

Among the accidents there was a case of revolver-shot through the upper half of the right lobe of the liver; recovery ensued without any bad results.

2. NATIVES.

Natives do not show so good results in medical cases as Europeans. They rarely come to hospital unless they are seriously ill and a very large proportion of the fatal cases are either unconscious on admission or become so soon after. Moreover, it seems quite a matter of indifference to a native whether he does or does not recover. It is interesting to note that the death-rate from fever and dysentery is higher amongst the natives than the Europeans, showing that mortality amongst the original occupants of a country is not a safe guide to what may obtain amongst newcomers. Natives stand pain, injuries, and surgical operations well and they recover with less disablement than one would expect. Tuberculosis is certainly demonstrable post mortem, although not common; when attacking the lungs it would appear from experience in this hospital to be more often disseminated than limited to areas of consolidation. Scurvy is also seen, at times similar to ordinary European scurvy and at other times aggravated by sub-periosteal hæmorrhage of the long bones of the legs, hæmorrhage into the muscles of the calf, along fasciæ such as the fascia lata of the thigh, and into the knee-joints. Such cases generally die from some complication such as dysentery, &c. Treatment seems futile; limejuice, raw meat juice, citrates of the alkalies, iodides, calcium chloride, iron, cod liver oil, and the whole list of supposed remedies for scurvy fail. One case of acute scurvy-rickets in a boy of about twelve or fourteen years of age is now in hospital and resisting all treatment. It is significant that natives confined in the gaol and others admitted here for prolonged treatment for, say accidents, frequently develop scurvy although no fault can be found with diet and surroundings. A "Kaffir small-pox" occurs here. One such case developed in hospital, with the usual premonitory symptoms of ordinary small-pox. The eruption which appeared on the fourth day was vesicular with some umbilicated and shotty spots and was distributed over the face and body generally. It is a disputed point whether such cases are genuine small-pox or an aggravated chicken-pox. The disease runs riot amongst the natives and sometimes leaves scars. It is apparently not communicated to Europeans, it is very rapid in the development and course of the eruption, and it is not very fatal. From the character of the eruption alone apart from other considerations it is impossible to distinguish it from European small-pox.

Measles, scarlet fever, diphtheria, and typhoid fever have not yet been found amongst natives at this hospital; syphilis is common and aggravated. Here are one or two cases of interest. A boy with a compound depressed fracture ¾ in. by ¼ in. of the right parietal bone close to the anterior superior angle walked up to the hospital; trephining was at once performed and the boy recovered completely. One boy was brought in dead from lightning stroke. The hair on the left temple was scorched. From the inner end of the left clavicle to the umbilicus ran a greyish narrow scar looking as though cigar ash had been rubbed along the skin; the epidermis along this scar readily rubbed off but the dermis revealed nothing and post mortem the appearances were negative; the pubic hair had been singed. The boy's clothes were wet, the right coat-sleeve was ripped open and his cap torn in two; in the pocket of his waistcoat was a penknife with the blade strongly magnetised. Of 4 cases of acute poisoning by arsenic 1 died with almost complete absence of gastric symptoms and marked cerebral symptoms closely resembling narcotic poisoning. A case of severe epistaxis of four days' standing yielded readily to administration of calcium chloride.

On June 30th the order of the Royal Red Cross was conferred on the matron of the hospital, the Rev. Mother Jacoba.

ABERDEEN WATER-SUPPLY.

THE Aberdeen Town Council has obtained exhaustive reports from the Professor of Pathology (Dr. D. J. Hamilton) and Dr. T. S. Murray, D.Sc., of the Chemical Department, University of Aberdeen, giving the results of detailed bacteriological and chemical examinations of the city water-supply. It may be explained that the water-supply of Aberdeen is taken from the River Dee at Cairnton about twenty-one miles from the city. From the intake to the settling reservoir at Invercannie, a distance of about one and a half miles, the water runs through a tunnel cut in rock. In this section a considerable addition of pure spring water is made to the supply, the quality of which it has been found to improve, while it does not appreciably affect the degree of hardness. The river water is very soft, a characteristic which leads to less consumption of soap and tea in Aberdeen than would otherwise be the case. From Invercannie to the service or distributing reservoirs near the city the water passes through an aqueduct (finished in 1866) which is composed of brick except at three points where it crosses small streams in cast-iron pipes under pressure. It was in consequence of complaints that the brick-work was not watertight and that impurities from cesspools, &c., found their way into the aqueduct that Professor Hamilton and Dr. Murray were instructed to draw up reports. The town council has established sewage irrigation farms at the villages of Kincardine O'Neil, Aboyne, Ballater, and Braemar above the intake, but in order to place the water-supply above suspicion has been considering whether a new source higher up the River Dee than Cairnton should be sought. To replace the present brick aqueduct by iron pipes would alone represent an expenditure of £125,000 and a scheme for new works from a source far up the country would probably cost nearly £500,000. Hence the desire to have scientific advice before coming to any definite resolution. As the result of a general survey of the amount of germ impurity found in the Aberdeen water Professor Hamilton says that the lowest number reached was 105 colonies per cubic centimetre on one occasion during very dry weather in the month of September, and the highest 5061 in the month of December after a heavy night's rain. The average over all points examined was 1862. He also found that whereas the water leaving the settling pond at Invercannie contained 3324 bacteria per cubic centimetre, the number rose in that entering the Mannofield reservoir after passing along the aqueduct, to 5061—a period of seventeen hours having intervened between the taking of the two samples. From these figures it would appear that the water had become distinctly contaminated in its transit. During the interval, however, it had been raining heavily, a circumstance which may have been accountable for the rise in the germ impurity. A sudden flush of rain, particularly after dry weather, is more effectual in raising the general impurity than any other natural factor, and this holds good not only of the ordinary supply from the river, but probably also of the water which gains entrance to the aqueduct through its walls. Notwithstanding occasional impurity of the jets, the water entering the aqueduct from extraneous sources, at least during dry weather, is, taken all in all, much purer than that of the river, and the admixture of this relatively pure water with the ordinary river-supply may aid in rendering the gross amount of germ impurity at the Mannofield exit less than at the Invercannie entrance. The relationship during the winter months between the colour of the water and the number of bacteria—that is to say, where the colour is high the bacterial impurity is also high—is usually pretty close but is not perfectly constant. The amount of sediment contained in the Aberdeen water is, Professor Hamilton continues, much greater than it ought to be. The brown residual matter found in certain water-pipes consists of dead vegetable substances, chiefly of peat moss, and while probably harmless—although this has been called in question—yet such sediment tends to harbour all sorts of minute animal life, such as small round worms (anguillula), infusoria, embryo leeches, &c. Portions of the slime scraped from the inside of the aqueduct swarmed with these round worms and infusoria, which were also found in considerable abundance in sediment from pipes. Professor Hamilton remarks that the quantity of gross sediment does not appear to bear any relationship whatever to the number of bacteria contained in the water. A much more constant indication of excessive germ impurity is a certain "milkiness" or turbidity which does not disappear on settling. He also found that it by no means follows because the organic impurity is high that the bacterial impurity will be high also. Very much the same may be said regarding the chlorine and the number of bacteria. Bacterial contamination was found to rise when the height of the river did so. The residual water in the aqueduct (when the water was turned off) was found to be relatively free from germ impurity, due to its being accumulated leakage, which in most cases must have filtered through the soil and become thereby purified, or been derived from springs in which the germ contamination is usually less than in any other water. This experience is not peculiar to the Aberdeen water-supply. But there is danger when polluted water runs through a crack or fissure in the soil, or where, from running continuously, it excavates a waterway for itself and mixes with the water-supply in an undiluted condition—as was actually verified by examination of one of the waterspouts in Aberdeen aqueduct, where the number of bacteria came up to 19,500 or 20,000 per cubic centimetre. The most prevalent organism found in this spout water seemed to be a variety of "proteus," one of the organisms found in putrefying animal substances. There may be several spots where highly contaminated water gains access to the aqueduct and Professor Hamilton dwells on the danger of this pollution as likely to spread water-borne diseases such as typhoid fever, cholera, and epidemic diarrhœa. Sand filtration, he adds, after the grains of sand become coated with slime consisting mainly of arrested vegetable matter, algæ, diatoms, &c., has an extraordinary effect in reducing the number of bacteria. The bacillus coli communis—an organism which inhabits the intestines of man and other animals and which is regarded as one of the characteristic bacteria of sewage—was looked for but discovered on only one occasion. The other organisms found are most likely harmless varieties. Professor Hamilton recommends (1) the furnishing of a water-tight aqueduct; (2) the purification of the water by means of settling ponds and filter beds; and (3) the removal, as far as possible, of all reservoirs, settling ponds, or other possible sources of contamination between the filter beds and the points of distribution in the city. Dr. Murray analysed 73 samples of the water. As to sediment, turbidity, and colour, he corroborates Professor Hamilton. In general the water was palatable and inodorous. The organic matter in the Aberdeen water is essentially of vegetable origin, owing chiefly to the extensive beds of peat on the higher gathering ground. Waters taken from Loch Muick and the River Muick were found to be unpolluted. No polluting influence from the irrigation farms was detected, but these farms may not prove completely equal to the work at the end of winter after prolonged frost. The filtering of the water is desirable and Dr. Murray considers that, in one way or another, the aqueduct should be made watertight. The water-supply was found to be of very varying quality.

BATTLE OF THE CLUBS.

EAST SUBURBAN MEDICAL PROTECTION AND MEDICO-ETHICAL SOCIETY.

THE membership of this society is open to "duly registered medical practitioners and other professional persons." The annual subscription is 10*s.* 6*d.* and the society's present address is at West Ham Hospital, E. The objects which the society has in view, as described at length in the memorandum of association, form a very comprehensive programme, the first five sections of which are as follows: (*a*) The investigation and the suppression of abuses in medical charities; (*b*) obtaining, or attempting to obtain, adequate representation of medical practitioners on the governing or managing bodies of medical charities; (*c*) suppressing, or attempting to suppress, medical aid societies and clubs which are not carried on by duly registered medical practitioners and in an honourable, professional, and satisfactory manner; (*d*) establishing a public medical service, a hospital, or dispensary chiefly managed by registered medical practitioners if and when

Digitized by Google

desired by a majority of the members in general meeting assembled; and (e) engaging, or assisting to engage, district, monthly, or other nurses for remuneration, to work under the sole direction of duly registered medical practitioners. The other objects include the undertaking of prosecutions, debt-collecting, carrying on a medical agency for the sale of practices, keeping a register of defaulting patients, &c.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6320 births and 5287 deaths were registered during the week ending Sept. 10th. The annual rate of mortality in these towns, which had increased in the eight preceding weeks from 14·7 to 24·4 per 1000, further rose last week to 24·6. In London the rate was 23·2 per 1000, while it averaged 25·5 in the thirty-two provincial towns. The lowest death-rates in these towns were 16·4 in Cardiff, 17·2 in Oldham, 17·3 in Portsmouth, and 17·4 in Swansea; the highest rates were 30·5 in Preston, 31·3 in Blackburn, 33·9 in Newcastle-upon-Tyne, and 35·5 in Salford and in Sunderland. The 5287 deaths in these towns included 1578 which were referred to the principal zymotic diseases, against 1541 and 1646 in the two preceding weeks; of these, 1318 resulted from diarrhœa, 82 from whooping-cough, 62 from diphtheria, 48 from "fever" (principally enteric), 39 from measles, 29 from scarlet fever, and not 1 from small-pox. The lowest death-rates from these diseases were recorded in Portsmouth, Cardiff, Swansea, and Huddersfield; and the highest rates in Wolverhampton, Preston, Bolton, Hull, and Sunderland. The greatest mortality from measles occurred in Plymouth; from scarlet fever in Wolverhampton; from whooping-cough in Sunderland; and from diarrhœa in Croydon, Wolverhampton, Blackburn, Bolton, Preston, Hull, and Sunderland. The 62 deaths from diphtheria included 30 in London, 5 in Manchester, 5 in Leeds, 4 in Swansea, and 3 in Birkenhead. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and only 3 small-pox patients were under treatment in the Metropolitan Asylum Hospitals on Saturday last, Sept. 10th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2300, against 2241, 2178, and 2240 on the three preceding Saturdays; 273 new cases were admitted during last week, against 187, 182, and 238 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 135 and 127 in the two preceding weeks, rose again to 130 last week, but were 18 below the corrected average. The causes of 42, or 0·8 per cent. of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Bradford, Hull, Newcastle-upon-Tyne, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Swansea, Norwich, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 18·1 to 19·8 per 1000, further rose to 23·0 during the week ending Sept. 10th, but was 1·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·7 in Perth and 20·7 in Paisley, to 23·8 in Greenock and 29·3 in Leith. The 695 deaths in these towns included 92 which were referred to diarrhœa, 22 to whooping-cough, 9 to measles, 9 to "fever" (principally enteric), 6 to scarlet fever, and 2 to diphtheria. In all, 140 deaths resulted from these principal zymotic diseases against 140 and 124 in the two preceding weeks. These 140 deaths were equal to an annual rate of 4·7 per 1000, which was 2·6 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 89 and 81 in the two preceding weeks, rose again to 92 last week, of which 45 occurred in Glasgow, 19 in Edinburgh, 9 in Dundee, and 8 in Leith. The 22 deaths from whooping-cough corresponded with the number recorded in the preceding week, and included 10 in Glasgow and 4 in Dundee. The deaths referred to different forms of "fever," which had been 9 in each of the four preceding weeks, were again 9 last week, of which 4 occurred in Glasgow and 4 in Paisley. Of the 9 fatal cases of measles 4 were recorded in Glasgow and 3 in Edinburgh. The 6 deaths from scarlet fever exceeded by 1 the number in the preceding week, and included 4 in Glasgow, where the 2 fatal cases of diphtheria were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 64 and 72 in the two preceding weeks, further rose to 100 last week, and exceeded by 22 the number in the corresponding period of last year. The causes of 32, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·4 and 27·6 per 1000 in the two preceding weeks, further rose to 30·7 during the week ending Sept. 10th. During the past four weeks the rate of mortality in the city has averaged 25·6 per 1000, the rate during the same period being 22·5 in London and 18·1 in Edinburgh. The 206 deaths registered in Dublin during the week under notice showed an increase of 21 upon the number in the previous week, and included 54 which were referred to the principal zymotic diseases, against 29 and 39 in the two preceding weeks; of these, 38 resulted from diarrhœa, 6 from whooping-cough, 5 from "fever," 2 from diphtheria, 2 from scarlet fever, and 1 from measles. These 54 deaths were equal to an annual rate of 8·1 per 1000, the zymotic death-rate during the same period being 6·3 in London and 4·2 in Edinburgh. The fatal cases of diarrhœa, which had increased from 4 to 33 in the seven preceding weeks, further rose to 38 last week. The 6 deaths from whooping-cough showed an increase of 2 upon the number in the preceding week. The deaths referred to different forms of "fever" which had been 3 and 1 in the two preceding weeks, rose again to 5 last week. The mortality from scarlet fever and from diphtheria also exceeded that recorded in recent weeks. The 206 deaths in Dublin last week included 63 of infants under one year of age, and 46 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further increase upon recent weekly numbers. Nine inquest cases and 7 deaths from violence were registered; and 59, or nearly a third, of the deaths occurred in public institutions. The causes of 13, or more than 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING AUGUST, 1898.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during August in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 6·5 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 7·2, 7·1, and 8·1 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, Westminster, St. James Westminster, Marylebone, Stoke Newington, St. Martin-in-the-Fields, Strand, and City of London; while they showed the largest excess in Fulham, Clerkenwell, St. George-in-the-East, Mile End Old Town, St. George Southwark, St. Olave Southwark, and Bermondsey. Five cases of small-pox were notified in London during August, against 1, 6, and 2 in the three preceding months; of these, 2 occurred in St. Pancras, 1 in Hackney, 1 in City of London, and 1 in Battersea sanitary areas. Two small-pox patients were admitted into the Metropolitan Asylum Hospitals during August, and remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a marked decline from that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Hammersmith, Fulham, Clerkenwell, Mile End Old Town, Poplar, St. George Southwark, Bermondsey, and Plumstead. The Metropolitan Asylum Hospitals contained 2207 scarlet fever patients at the end of August, against 2147, 2146, and

2255 at the end of the three preceding months; the weekly admissions averaged 202, against 223, 208, and 242 in the three preceding months. The prevalence of diphtheria in London during August also showed a marked decline from that recorded in the preceding month; this disease was proportionally most prevalent in Fulham, Holborn, Clerkenwell, St. Luke, Newington, and Battersea sanitary areas. There were 865 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of August, against 917, 971, and 1014 at the end of the three preceding months; the weekly admissions averaged 107, against 134 and 146 in the two preceding months. The prevalence of enteric fever in London showed a further increase upon that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Westminster, Hackney, Shoreditch, Bermondsey, and Greenwich. The Metropolitan Asylums Hospitals contained 118 enteric fever patients at the end of August, against 54, 53, and 87 at the end of the three preceding months; the weekly admissions averaged 21, against 8, 11, and 16 in the three preceding months. Erysipelas was proportionally most prevalent in St. Giles, Bethnal Green, St. George-in-the-East, Mile End Old Town, and Rotherhithe sanitary areas. The 14 cases of puerperal fever notified in London during August included 2 in Hackney, 2 in Wandsworth, and 2 in Greenwich sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, Sept. 3rd, the deaths of 8949 persons belonging to London were registered, equal to an annual rate of 20·7 per 1000, against 15·7, 14·6 and 14·7 in the three preceding months. The lowest death-rates in the various sanitary areas were 11·5 in Hampstead, 11·6 in St. George Hanover-square, 13·6 in London City, 15·7 in Marylebone, 16·0 in Lee, 16·5 in Stoke Newington, and 16·6 in St. Olave Southwark; the highest rates were 24·9 in Newington, 25·5 in St. Saviour Southwark, 28·2 in St. Luke and in Shoreditch, 28·3 in St. George-in-the-East, 28·8 in St. George Southwark, and 29·2 in Limehouse. During the five weeks of August 2344 deaths were referred to the principal zymotic diseases in London; of these, 1875 resulted from diarrhœa, 156 from whooping-cough, 121 from diphtheria, 94 from measles, 48 from enteric fever, 47 from scarlet fever, 3 from ill-defined forms of continued fever, and not one either from typhus or small-pox. These 2344 deaths were equal to an annual rate of 5·4 per 1000; among the various sanitary areas the lowest zymotic death-rates were recorded in St. George Hanover-square, St. James Westminster, Hampstead, St. Martin-in-the-Fields, Strand, and London City; and the highest rates in Fulham, St. Luke, Shoreditch, Limehouse, Poplar, St. George Southwark, and Newington. The 1875 fatal cases of diarrhœa were as many as 833 above the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Fulham, St. Luke, Shoreditch, Limehouse, Poplar, St. George Southwark, and Newington sanitary areas. The 156 deaths referred to whooping-cough almost corresponded with the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Holborn, St. Luke, Limehouse, St. George Southwark, Lambeth, and Woolwich. The 121 fatal cases of diphtheria were 77 below the corrected average number; this disease showed the highest proportional fatality in Fulham, Chelsea, Hampstead, Mile End Old Town, Newington, and Battersea sanitary areas. The 94 deaths from measles were less than half the corrected average number; among the various sanitary areas the mortality from this disease was highest in Islington, St. Luke, Shoreditch, Bethnal Green, St. George-in-the-East, and Lee. The 48 fatal cases of enteric fever were 6 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 47 deaths referred to scarlet fever were 58 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. James Westminster, St. George Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was as much as 32 per cent. above the average, owing to the excessive fatality of summer diarrhœa.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was equal to 316 per 1000, which very considerably exceeded the average, owing to the fatal prevalence of infantile diarrhœa. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, Westminster, St. James Westminster, Marylebone, Hampstead, London City, and St. Olave Southwark; and the highest rates in St. Pancras, Holborn, Shoreditch, Limehouse, Poplar, St. Saviour Southwark, St. George Southwark, and Battersea.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: Jeremiah Sugrue to the *Dido;* Anthony Kidd to the *Isis*, and Edward J. Morley to the *Australia.* Surgeons: Richard A. Ross to the *Dido;* Harold G. T. Major to the *Isis;* and John A. Keogh to the *Jupiter.*

ROYAL ARMY MEDICAL CORPS.

Captain William Perceval Gore Graham retires from the service, receiving a gratuity. Surgeon-General Catherwood is selected for the appointment of Principal Medical Officer at Bengal, vice Surgeon-General Masham, retiring, and Colonel Pollock succeeds Colonel Catherwood as Principal Medical Officer at Gibraltar.

INDIA AND THE INDIAN MEDICAL SERVICE.

Captain Bird, Resident Medical Officer, Medical College Hospital, Calcutta, is appointed in addition to his own duties, to act as Professor of Physiology, Medical College Hospital, until further orders. Captain Clarkson, on return from temporary military duty, is appointed to act as Civil Surgeon of Nadia during the absence on deputation of Captain Dare, or until further orders. Major Waddell (Bengal), Chemical Examiner and Professor of Chemistry in the Medical College, Calcutta, is granted special leave on urgent private affairs for six months.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant David R. Dobie, M.D., 2nd Volunteer Battalion, the King's Scottish Borderers, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd Cinque Ports (Eastern Division, Royal Artillery): Shepherd McCormick Boyd to be Surgeon-Lieutenant. 2nd Devonshire (Western Division, Royal Artillery): Leonard Leighton Hanham to be Surgeon-Lieutenant. 4th West Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Captain C. N. Gwynne to be Surgeon-Major, to resign his commission, with permission to retain his rank, and to wear the uniform of the corps on his retirement. *Rifle:* 7th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Major J. L. Crombie to be Surgeon-Lieutenant-Colonel. 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment): John Wayte to be Surgeon-Lieutenant.

THE RECENT MANŒUVRES.

Now that the manœuvres are over there is an opportunity for taking a brief retrospective view of what has been done. In the first place the weather throughout the operations was very hot—indeed sub-tropical—temperatures of 90° F. in the shade and 112° in the sun having been commonly reached. The men bore the heat and their fatigues and privations, for there were privations, well and cheerfully. The health of the troops was excellent, the sickness having been from 1 to 2 per cent., and the diseases were of a relatively trifling nature. The physique and marching powers of the troops were excellent, and we have reason to know that many officers and spectators were very agreeably surprised at the good quality of the material they saw, and at the numbers, military bearing, and physical appearance of the troops. There was comparatively but little falling out, and take them for all in all both Army Corps consisted of sturdy, active and well-set-up soldiers. The Royal Engineers' arrangements were very good. Water was a difficulty owing to the supply not being by any means so abundant as could be desired. Great care was taken to protect it from contamination. Officers commanding battalions and officers of junior rank can only see what is going on in their

Digitized by Google

immediate vicinity; they can know little or nothing of the strategical and tactical objects of the military movements. The main benefits to be derived from big military manœuvres are reserved for the generals commanding and their staffs. As regards strategy the commanders of each side had very little initiative allowed them and they had comparatively little, instead of absolute, freedom of action to deal with the actual situation as it presented itself and varied from time to time. One well-known firm undertook to supply the canteens, which is a very different thing to supplying an army in the field, a large number of things being provided in the one case which could not be furnished, or expected to be furnished, in the other. Another well-known firm supplied the hired transport. Transport is always a great practical difficulty in war and it is unfortunately the pivot on which so much depends in a campaign. The employment of civilian horses, drivers, and carts was by all accounts far from a success. It is a very general and popular belief that big contracting firms could do everything better for a force than the regular transport and supply branches of the army, but the experiment on this occasion should convince people that it is an uncommonly difficult thing to deal satisfactorily with the conditions presented by an army in the field—conditions which are quite novel to contractors. Organisation and discipline are absolutely essential in all undertakings of this kind, and the Army Service Corps did their work in a more efficient and better way than their auxiliary civil aids, only that corps was too weak, owing to the Egyptian and other campaigns, to undertake the task unaided. It is well, however, that the civil experiment has been made, because its shortcomings can be guarded against by better arrangements in the future. Lord Wolseley has called for information and full returns to be furnished to the War Office in connexion with the manœuvres. We have every reason to believe that, as far as the arrangements of the Royal Army Medical Corps were concerned, they were satisfactory and worked well.

THE LATE SPANISH-AMERICAN WAR.

The sufferings of the American soldiers from disease—especially of those of the force recently operating in Cuba—have been very great and continue to cause much indignation among the American people, whose conscience has been keenly aroused in this respect. Nothing could have exceeded, by the way, the kindness of the people to these unfortunate American soldiers; it was quite conspicuous. In addition to the malarial and climatic fevers and other disorders which may be fairly attributed to active service in Cuba, there has also been a lamentable prevalence of enteric fever among the American troops recently employed there and elsewhere. The food, it is alleged, supplied to the Cuban force was unsuitable, the hospital accommodation and sick supplies were insufficient for the purpose, the land transport was inadequate, and the shipping transport for the sick and wounded left much to be desired in various ways. Moreover, several of the military camps in America, owing to their having been badly selected and insanitary, are stated to have given rise to much preventable disease. The whole subject is, it is understood, to be investigated and reported upon by a Commission appointed by the United States Government.

GALLANTRY OF FRENCH MEDICAL OFFICERS IN THE FIELD.

The French navy has reason to be proud of its medical officers. In addition to Dr. Abbatucci, whose decoration for Soudan services was recently mentioned in this column,[1] another young naval surgeon has been rewarded with the Cross of the Legion of Honour for gallant conduct before the enemy in Madagascar. When the outpost at Bekapoka was attacked last September Dr. Rapuc, rifle in hand, ably seconded the efforts of the lieutenant in command, and by his *sangfroid* and energy materially contributed towards the discomfiture of the assailants. The following month also, while on a medical tour, this officer succeeded in effecting the escape from the rebels of almost the whole of his escort after their leader, a European sergeant, had been mortally wounded. In the same gazette the special promotion of yet another naval medical officer, Dr. Emily, is recorded on account of "exceptional services in the Oubanghi district," while a member of "the Marchand mission."

[1] THE LANCET, June 18th, 1898, p. 1718.

DEATHS IN THE SERVICES.

Surgeon-Major-General Inkson, A.M.S., retired, at Acton, on Friday, Sept. 9th, at the age of sixty-two years. He served with the Baltic Expedition of 1855, including the bombardment of Sweaborg. He was appointed an Assistant Surgeon in the Army in October, 1857. The following year he served in the Indian Mutiny campaign, including the capture of Jugdespore and three subsequent actions in October, for which he had another medal. In 1865 he was again employed on active service, this time with the Bhootan Expedition, for which he had a third medal. Surgeon-Major in March, 1873, Brigade-Surgeon in 1883, and Surgeon-Colonel in September, 1888, he became Surgeon-Major-General in 1893 and was placed on the retired list in November, 1895. The late officer was an M.D. of Edinburgh University and L.R.C.S. Edin.

Among the appointments on the personal staff of Sir William Lockhart on his assuming the command of the forces in India we notice the name of Captain Beyts, R.A.M.C., as surgeon to the Commander-in-chief.

Correspondence.

"Audi alteram partem."

THE SO-CALLED CONSERVATIVE SURGERY OF THE UTERINE APPENDAGES.

To the Editors of THE LANCET.

SIRS,—As Mr. Christopher Martin owes his education, experience and advancement in gynæcology entirely to me it is something more than a disappointment to find that he ignores or forgets some of the best instruction I ever gave him. What he refers to in his paper as valuable additions made by German authorities of recent years is merely and for the most part the discarded work of English operators of a time when Mr. Martin wore jackets. The first real piece of conservative work on the ovary and its tube was when Bantock and I discovered, almost simultaneously, that parovarian tumours could be removed entirely by enucleation and showed that they should not be classed for any purpose whatever with tumours of the ovary. From that time I have never ceased to argue that in cases of broad ligament cysts, which constitute at least 10 per cent. of all the cases reckoned as "ovariotomies," the healthy ovary and tube should be left alone. This is the only successful piece of conservative surgery in the pelvis with which I am acquainted and its success is not constant. The broad ligament is a piece of peritoneum and the ovary and tube are covered with it. If you injure the peritoneum or if inflammatory action is in any way excited in it it lies against another peritoneal surface and inevitably (so at least it appears) becomes adherent to it. If a Fallopian tube or ovary is injured they become adherent and after a time, usually years, they become cirrhotically atrophied and cause endless suffering and trouble, and their removal under these circumstances includes by far the most difficult pelvic operations we have to encounter, operations which many of those who attempt them leave unfinished and say nothing about them. On these points I have published over and over again and I have published series of cases showing that by reason of these peculiar complications the secondary operations are fatal to a terribly increased degree. The facts of these adhesions and the difficulty of overcoming them being known only to the fingers of the men operating were much doubted till I was able to show the celebrated specimens given to me by Sir Henry Littlejohn and then all doubt was set at rest.

Mr. Christopher Martin passes all this by and derives much comfort from the word "conservative." The term "conservative surgery" was invented in the reign of the late Sir William Fergusson and was greatly supported by him. Large numbers of operations of the "conservative" order were done and the victims were sent out of hospital. But in looking over the operation lists of our large hospitals now I am greatly comforted by seeing that the "conservative" class of operations are hardly performed now at all, certainly not as they were, and that flail-like limbs have gone out of fashion.

Digitized by Google

It is difficult to see why this second wave of "conservative surgery for the uterine appendages" should have its existence, for no suggestion in it has been made, but one, which was not tried in my *clientèle* in the early "eighties." That exception is "ignipuncture," though as a perfectly certain exciter of the process of peritoneal adhesion it is the last thing which could have occurred to me as reasonable.

Finally, this "conservative surgery for the uterine appendages" is to include removal of a perfectly healthy uterus. I have shown some eight or ten years ago that secondary removal of the uterus is sometimes necessary to relieve symptoms continued after removal of diseased tubes and ovaries, some 6 or 8 per cent. of the cases requiring this secondary proceeding. But any effort to make removal of the uterus an essential part of the first operation will have my strongest disapproval. Mr. Martin exaggerates the number of cases in which vulvar and vaginal atrophy occurs after removal of the appendages, but he will immensely increase it in reality if he removes the uterus with them. Further, there are strong reasons, which I have not space to give here, why in dealing with cases in which the neurotic element is a preponderating factor the uterus should be left. This subject I hope to deal with at length before long.

In conclusion, let me beg Mr. Martin and my younger brethren generally not to fall into the pit of neglecting to read what has gone before them, even in the generation immediately preceding them. Between the years 1870 and 1894 a good deal was done in Great Britain for gynæcology, and on the conservative aspect of the case we have nothing, absolutely nothing, for which we have to be beholden to our German brethren.—I am, Sirs, yours faithfully,

Birmingham, Sept. 12th, 1898. LAWSON TAIT.

THE PITCH OF THE HUMAN VOICE.

To the Editors of THE LANCET.

SIRS,—Has it been observed that some ratio exists between the set of the human ear and the (singing) pitch of the voice? During my holiday I have amused myself by forecasting the qualities of their voices, whether deep-toned or otherwise, before the vocalists whom I have met have sung. The inference is drawn from the squareness or angularity of the jaw and from the mode in which the ear is set on to the cheek, whether vertically with the face or obliquely; if vertically then a deep-toned voice belongs, but if the ear slants downwards and forwards a tenor or soprano voice accompanies. A better anatomist than myself will probably explain the reason.

I am, Sirs, yours faithfully,

ALEXANDER WALLACE, M.D. Oxon.

Colchester, Sept. 10th, 1898.

"THE PLAISTOW MATERNITY CHARITY."

To the Editors of THE LANCET.

SIRS,—To reply fully to Mr. Pritchard's letter in THE LANCET of Sept. 10th would require more time and space than his special pleading merits, but the last paragraph, in which he infers that we who employ nurses from this Home are therefore satisfied with them, claims a prompt denial. It is a case of Hobson's choice. The conditions under which we practise our profession in Plaistow make a nursing institution supported by charitable funds a necessity.

We are obliged to employ these nurses because they are the only ones available and we naturally express our thanks for the help we get. But at the same time we almost unanimously condemn the maternity department and find the training of nurses leaves much to be desired, for the nurses are responsible to a superintendent nurse and not to us and frequently our instructions are not carried out. Mr. Pritchard's "more important practitioners" will hardly thank him for the insinuation that they make use of these charity nurses, not only to enable them to keep paying patients, but even to tout for them

I am, Sirs, yours faithfully,

Plaistow, Sept. 13th, 1898. P. NAPIER JONES.

*** In the letter from Mr. W. W. Farnfield, headed "The Plaistow Maternity Charity," printed in THE LANCET of Sept. 10th, the last three lines should have read: "St. Mary's Day Nursery and Hospital for Sick Children, Plaistow, E., is in no way connected with the Plaistow Maternity Charity."

"A CASE OF MEMBRANOUS TRACHEITIS AND LARYNGITIS WITHOUT THE PRESENCE OF DIPHTHERITIC BACILLI."

To the Editors of THE LANCET.

SIRS,—The interesting case reported by Mr. Grimes under the above heading in THE LANCET of August 13th of membranous tracheitis and laryngitis in which no diphtheria bacilli were found, draws attention to a circumstance in regard to diphtheria which is not sufficiently recognised—viz., that the term "diphtheria" requires to be now considered in a double sense. First, we have the clinical form in which the leather-like membrane from which the word "diphtheria" was derived is the prominent feature. The conclusion of the Royal Medical and Chirurgical Society's committee of 1875 that such a membranous laryngitis is identical with true diphtheria has been allowed to give too much colour to all statements on this point from English authors. It is, however, now generally recognised that in a certain proportion—14 per cent. according to Billings—there may be a membranous laryngitis or tracheitis not truly diphtherial according to the bacteriological test. I have reported such a case in my monograph on Diphtheria at p. 181. The responsible organisms in this instance were streptococci and staphylococci. Mr. Grimes does not state what they were in his case. The second form of diphtheria to which I have alluded is the bacillary, in which the clinical evidences of membrane are but very slight or may be entirely absent. According to Variot and other observers the prognosis of this form is very favourable. May I, in conclusion, once more plead that since Trousseau gave his reasons for substituting the word "diphtheria" for "diphtheritis," the use of the adjective "diphtheritic" should give way to "diphtherial"? Certainly the term "diphtheritic bacilli" does not accurately describe the Klebs-Löffler organisms of the malady.

I am, Sirs, yours faithfully,

LENNOX BROWNE, F.R.C.S. Edin., M.R.C.S. Eng.

Mansfield-street, W.

UNTOWARD RESULTS AFTER ADMINISTERING RESORCIN.

To the Editors of THE LANCET.

SIRS,—Recently I was called in consultation with another medical man to see a child and we prescribed resorcin in 2 gr. doses. The mother states that a quarter of an hour after the powder had been administered the child's mouth became inflamed and the tongue was swollen. When I saw the child the following morning blisters had been formed on the lips similar to what would have been produced by boiling water, and in addition to a thick white coating on the tongue there was a distinct excoriation outside the mouth. On making inquiries we found the drug dispensed had been exposed to light and presented the appearance of decomposition having taken place and it occurs to us that carbolic acid or other irritant may have been produced. The chemist we have reason to believe has suggested to the parents that the injury was due to the drug having been administered without a vehicle. We have never known or heard of severe results of the kind being produced by pure resorcin and we think that in the present instance decomposition or the substitution of another drug may have had much to answer for. Perhaps I ought to have mentioned that the child was suffering from cholera infantum. I enclose some of the powders and we will feel much obliged for your opinion.

I am, Sirs, yours faithfully,

Sept. 5th, 1898. L. C.

*** We have submitted the powders to our analyst for examination in THE LANCET Laboratory, but no evidence was gained that they contained anything but resorcin. The papers enclosing the powders were slightly discoloured, due to partial oxidation, resorcin especially in association with alkali absorbing oxygen from the air much in the same way as its analogue pyrogallol. Our correspondent will

Digitized by Google

find a reference on the pharmacology and therapeutics of resorcin in THE LANCET, vol. ii., 1880, p. 777, and vol. ii., 1881, p. 1065, in which it is stated that resorcin has a caustic action on the skin, and application to the moist lips causes a white eschar.—ED. L.

THE ABUSE OF NURSING CHARITIES.

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 580.*)

THE first result of the attempted organisation of the medical practitioners was to retard the opening of a branch for the extension of the Plaistow Maternity Charity and District Nurses' Home to the East and West Ham districts. It was not till August 4th that the projected branch was opened. It is situated in East Ham and it is a significant fact that no medical man in that district has consented to attend to such midwifery cases as proved to be beyond the competence of the nurses. The nurses are therefore obliged to send for medical assistance to a practitioner living in the West Ham district. The feeling is strong among the members of the profession that in thus extending this nursing institution the cases of abuse will be considerably increased. As a further proof that such abuse existed several medical men related to me that they had been called in because the nurses had not given satisfaction and that in such cases they received fees of a guinea and upwards. How was it that these charity nurses were in attendance on persons who could afford to pay guinea fees? and for one person who was dissatisfied with the nurse and therefore called in a medical practitioner, how many have contented themselves with the nurses' services and not called in any medical adviser though they could well afford to pay his fee? Another local practitioner related that he had been retained to attend a woman in her confinement who could afford and had promised the usual fee. As the time drew near this woman, however, changed her mind, did not send for her medical man, but secured the services of one of the charity nurses instead. Complications arose at the confinement, the husband was alarmed and came to fetch the medical man whose services had been originally retained. When, however, my informant, the medical man in question, reached the house he found that the nurse, with other nurses to help her, had profited by the husband's absence to have the patient removed to the hospital. Here, then, we have a double abuse. Firstly, a woman who can afford to pay and had actually retained her medical attendant is persuaded at the last moment to accept instead the services of a charity nurse who should be attending only to the poor. Secondly, as the case turns out badly, the patient is carried off to the hospital while her husband has gone out to bring in the local practitioner. Thus the practitioner is deprived of his case first by the charity nurses and then by the hospital, and this was a patient who could afford to pay.

The question of the attitude that the local practitioners should observe towards these nurses is somewhat complicated and delicate. Thus a general practitioner related to me that a nurse from the Plaistow Maternity Charity came to him and asked for his assistance in a case of retained placenta. The nurse said that she had been to several other medical men and they had all refused to have anything to do with the case. My informant likewise refused. He argued that medical men should not be thus utilised at the last moment to get a nurse out of a scrape. If medical men were available on such emergencies the nurses would go round saying that a medical man was sure to follow them if needed. The patients would then not be afraid to employ only nurses and the latter would trade on the fact that they could call in the nearest practitioner if any trouble arose. This would be all the more useful to the nurses from the Plaistow Maternity Charity, as they are often too far away to get help from that institution. On the other hand, it may be argued with much force that when a life is in danger the medical practitioner should not refuse his services, even though he may by such help be aiding some system of undercutting his own profession. Perhaps the formation of a strong union may provide the answer to this problem. Alone and unaided the refusal to attend such cases is the only means of defence which the local practitioners possess, but if they have a strong union behind them they might perhaps attend, and this not only from motives of humanity, but so as to better investigate and expose the case. A strong organisation can expose a case of abuse where an individual acting alone would fail to do so. Then, again, if it be nevertheless necessary under certain circumstances to refuse attendance, it would be better that these circumstances should be clearly defined by a medical union and not by an individual practitioner. Such a decision also should be made public. It would be most lamentable and injurious to the cause of organisation if a woman in confinement lost her life because she had in her ignorance engaged a nurse in a manner not acceptable to the members of the medical profession. At least it should be made clearly evident that the widest publicity had been given to the fact that under certain clearly defined conditions medical practitioners would refuse to attend. Indeed, this refusal to attend is probably the most powerful weapon in the hands of the profession, but it must be employed with great prudence and only after the matter has been thoroughly discussed and the policy approved and sanctioned by the union. It is needless to point out the utter futility of one practitioner refusing to attend. But in this particular instance several practitioners declined to attend. There seems therefore to have been good reason for such an attitude. Then let those reasons be produced; let the union to which these gentlemen belong, the East Suburban Medical Protection Society, investigate the matter closely. If this policy of refusing to attend a case of confinement when an emergency arises and a nurse seeks to cover her responsibility is approved, the precise conditions under which it may be anticipated that medical men will withhold their services should be made widely known. This would indeed be a very effective manner of checking certain phases of abuse.

Of course such grievances are not confined solely to the Plaistow Maternity Charity and Nurses' Home. For instance, at Leytonstone a patient retained the services of her medical attendant for her confinement, the fee agreed upon being one guinea. The patient likewise engaged a nurse from the Essex Cottage Nursing Homes, which is a charity supported by voluntary contributions and by entertainments. The nurse was paid 5*s.* for her services. These nurses attend to midwifery cases for 5*s.* and the nurse in question was surprised to find that a medical practitioner had also been engaged. The nurse even went so far as to protest that this was in no way necessary. The patient, however, persisted in her resolution; she could afford the guinea and therefore she meant to have a fully qualified medical man to attend upon her, and the medical man in question related to me the incident; but, as he pointed out, for one person who acts in this manner how many are there who would easily allow themselves to be persuaded and would trust themselves entirely to the nurse, who charges only 5*s.*? Yet I am told that the nurses from the Essex Cottage Nursing Homes have no qualified practitioner to assist them. At Ilford, also, there is a nurse who is canvassing the medical men's patients for midwifery cases. She tells the people that all medical men charge at least a guinea for confinements and that she will take 5*s.* or 7*s.* 6*d.* Out of this there arises incidentally a curious question. A medical practitioner must not employ an unqualified assistant, but he is quite at liberty to send for this unqualified nurse and get her to take over some of his midwifery cases whenever he has not time to attend to them fully himself. It seems illogical that nurses may be employed, however incompetent they may be, while the unqualified assistant, though often competent and possessing considerable experience, must not be employed. Such in any case was the question which arose when discussing the position of the unqualified nurse who is canvassing for midwifery cases at Ilford. Doubtless as medical union becomes stronger and better organised we shall hear more and know more of the evils which arise from midwifery cases being left in the hands of incompetent persons.

What can be done by united action can be seen in the east suburban district of Loughton. About two years ago some charitably disposed inhabitants of Loughton wanted to establish a nursing charity. A nurse was to be imported into Loughton for the purpose of attending midwifery cases among the poorer sections of the population either for nothing or for very small fees. Fortunately the local practitioners at once took action. They were quite unanimous and declared

Digitized by Google

that such a charity would interfere with the trained nurse and the medical men established in the locality. The proposed nursing charity was successfully nipped in the bud. Instead of indiscriminate charity there is at Loughton a Maternity Club. The mothers subscribe some months in advance to this institution and when they are confined they are attended by one of the local fully-qualified practitioners and the club pays him a guinea fee. At first the subscriptions paid by the mothers did not suffice and the balance was made up by donations from charitable persons. Now, however, the Maternity Club has ceased to be a charity the members subscribe enough not only to pay the guinea fee to the medical attendant, but also to pay a nurse and to get various things specially needed at such a time. Thus there are no midwifery cases attended in Loughton for less than a guinea and one of the local practitioners assured me that during the last four years he had had no bad debts and he had not even been put to the unpleasantness of having to ask for his money. It is true that the inhabitants of Loughton are fairly prosperous. They work for the railway, for corn-merchants, and as gardeners for the local residents. The most improvident belong to the mixed gipsy class. They are not true gipsies, for when a number of gipsies were turned out of Epping Forest some of them married East-end women and thus a sort of half-breed race has grown up. They live by providing donkeys and various sorts of entertainments for the holiday folk who visit the forest. These are the only class of people at Loughton likely to give the local practitioners some trouble. There is a provident society at Loughton which is self-supporting and there are benefit societies and medical aid associations. These all pay 1*d.* a week for adults, but for children they pay less. However, as the population is exceptionally healthy and there is very little sickness these sums represent more than they would in a large town and I did not hear any complaints. The nurses from Plaistow and other and nearer nursing institutions do not come to Loughton. Yet the poor have an efficient nurse to attend to them. This is one of the "Queen's nurses" and she costs the community about £100 a year. The money is raised by subscription and managed by a committee on which the interests of both Church and Chapel are duly represented. The nurse has a cottage to live in, must not accept any fee, and only attends to others than the poor in a case of emergency. If an accident happens to a well-to-do person and the help of a nurse is required immediately then the medical attendant may send for this nurse, but she must leave the case as soon as a paid nurse has been brought down from London. It is therefore only in cases of emergency that the Queen's nurse can be employed, and on those occasions the person profiting by her services is supposed to contribute half a guinea towards her maintenance. Such a case, however, is of rare occurrence. The nurse's time is devoted to attending the poor, but she must only visit patients to whom she is sent by one of the medical men of the town. Thus the matter is entirely in the hands of the local practitioners: the nurse is there to help them and not to compete against them. The inhabitants of Loughton seem to have realised that it is the business of medical men to attend to the sick and that the best way of helping those who are ill is to help medical men to do their work. Efficient nursing is a great help; the grievance at Plaistow, East Ham, and elsewhere is not against nurses who help, but against nurses, most of them insufficiently trained, who compete against fully-trained nurses and against the medical practitioners. The fact that such a grievance does not exist at Loughton, though it prevails extensively in the immediate neighbourhood, shows what the profession can do when its members are united, and it indicates also that there is a way out of the difficulty.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Third Outbreak of Plague in Bombay.—New Measures and their Probable Consequences.—Appointments of Divisional Health Officers.—Plague elsewhere.

IT cannot be disguised that Bombay is seeing the commencement of a third outbreak of the plague epidemic. The deaths during the past week have risen from 101 to 162, the type of the disease appears to be extremely virulent, and the cases are occurring in all parts of the city. Considerable anxiety is being felt and expressed in trade circles with regard to the probability of severe plague regulations being again enforced. The continuous expenditure on plague measures is also telling seriously in many quarters, and has virtually brought the finances of the Bombay Government to insolvency. The new plague powers and organisations are much the same as the old, but instead of the Plague Committee the Municipal Commissioner becomes the responsible chief plague authority. As he is interested in the municipality, and especially in its finances, whatever plague measures may be enforced will at least be subject to proper financial control.

The denial of the riots of last March being premeditated is only an official defence of departmental policy. No one believes it. I have been given an intimation that if the former obnoxious measures be reintroduced rioting will be repeated. The plague regulations being so distasteful the native leaders seek for means of counteracting them. The loss of a few lives is nothing to them and is admitted as such. They recognise the results of the last riots and almost regret that they were not brought about before, and they have the foresight to see that the enforcement of sanitary measures which lead to disturbance will assuredly be condemned and consequently withdrawn. A fight against disease when the people are against you cannot be conducted at the point of the bayonet. This, I believe, is the native opinion and indicates their future policy. If the new powers placed in the hands of the Commissioner be carried out with the martial spirit and with the military assistance of the late Plague Committee the rioting will be repeated. In view of the developing third outbreak it is to be hoped a more sympathetic course will be adopted.

In the reorganisation scheme for the Health Department of Bombay city 4 divisional health officers have been appointed. Dr. C. H. Cayley has been given No. 1 division, comprising the south of the island and the eastern district of the city. Mr. J. Leask has No. 2 division, comprising the western and central districts of the city; Mr. W. Venis No. 3 divison, comprising the northern part of the city; Dr. S. C. Hormasjee (a Parsee) No. 4 division, comprising the whole of the suburbs on the north. As Mr. J. Leask is not a medical man his appointment to such a post is a curious anomaly. His powers for administrative work are undoubted and he has acted as the assistant health officer for some years. Personally nothing but praise can be said in his favour, but in principle the appointment is wrong. Some other post might well have been given to him in order to secure his services to the corporation.

In other places plague seems more intense than it has ever been in Bombay. Dharwar district shows a death-rate of 82 per cent., Thana district of 78 per cent., Satara district of about 80 per cent., and Belgaum of 77 per cent. Also a much larger proportion of the population has been attacked. The ridiculous rules made for the English nurses at Calcutta and previously reported were withdrawn soon after they were made publicly known by the press.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Infectious Diseases at Health Resorts.

IN his report on the health of Manchester for the second quarter of this year Dr. Niven draws attention to the frequency with which children contract scarlet fever and other infectious fevers at "health resorts" and to the little solicitude shown by heads of families that the quarters selected should present a clean bill of health. He points out that at most of our health resorts there are powers for the compulsory notification of infectious disease and that visitors may obtain reliable information from the local medical officers of health. It is to be feared, however, that the danger of infection cannot always be met in this way, for there is no doubt that many children are taken to these places after suffering from scarlet fever and before desquamation is finished and after measles before they are free from infection. It is clearly the duty of medical practitioners to do all they can to prevent their patients being moved before they cease to be dangerous to others.

Poisoning Attributed to Potted Shrimps.

Some 40 or more people at St. Anne's-on-the-Sea have

Digitized by Google

been made violently ill with sickness and diarrhœa from eating potted shrimps. At all events, that has been the local belief. The Lancashire coast is famous for its shrimps and it would be a serious misfortune if they were to lose their character. The shrimp-nets are plied for some miles along the coast, where a deep channel divides the foreshore from the shallow banks. It is said that the shrimps were caught, potted, and used the same day. No deaths have occurred, though some of the cases were serious. The fishermen say that the shrimps were caught where there could be no sewage pollution.

An Anti-vaccinator.

The first application under the recent Vaccination Act was made to Mr. Headlam, the stipendiary magistrate, at the Manchester city police-court on Sept. 8th. The applicant said his child was ten months old, and he asked what he should do under the circumstances, as he had not got all his papers and was going on a three months' journey. The magistrate recommended him to have the child vaccinated and after some discussion told him to make another application.

Conference on the Sewage Question.

A meeting of representatives of local authorities in the Irwell watershed, called by the River Irwell Conservancy Committee of the Salford Corporation, was held yesterday at the Salford Town Hall to consider the question of sewage disposal by land treatment. The chief outcome was a strong protest against the insistence by the Local Government Board in every case on land being purchased for the treatment of sewage. It still demands "that for every 20,000 of population ten acres of suitable land should be adopted for land filtration" whether it was possible or impossible to obtain the land. It was stated that in the Swinton and Pendlebury districts preparation had been made for the bacteriological treatment of their sewage and the effluent was satisfactory to the Mersey and Irwell Joint Committee. "But the Local Government Board would not give them power to sewer a certain portion of their district that was at present unsewered unless they undertook to buy 125 acres of land in addition to the 33 acres they had at present." It was moved: "That it be recommended that an association be formed of the local authorities within the Irwell watershed to be composed of two representatives of each authority to fully consider and report upon the following matters—namely: (*a*) the requirements of the Local Government Board with respect to filtration of sewage effluent through land; (*b*) the rights of manufacturers to turn trade liquids and refuse into the public sewers; and (*c*) the standard of purity of the effluent required by the Mersey and Irwell Joint Committee, and that each authority be required to contribute towards the incidental expenses *pro ratâ* according to population."

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Sanitary Association of Scotland.

THE twenty-fourth annual congress of this association has during the past week been in session at Rothesay, receiving a cordial welcome from the inhabitants, who were represented by the Marquis of Bute, the honorary President of the association. The President for the year is Dr. Archibald K. Chalmers, one of the medical officers of health of Glasgow. The subject of the Presidential Address was the Vital Statistics of School Ages. Dr. Chalmers took the years between the fifth and fifteenth as representing approximately the school period and showed by statistics that this period contained the healthiest years of life. Comparing the figures for 1890-92 with those for 1870-72 it appeared that the death-rate for the school age during the former period was less by 38 per cent. than during the latter. The causes of death during the school period were discussed in detail and figures were produced to show that the fatal influence of zymotic and tuberculous diseases had been very considerably reduced; also by comparison of the figures for diseases of the nervous system it was claimed that no support, but the opposite, was afforded to the contention that over-pressure in schools exercised a prejudicial influence on the nervous systems of the children. Diseases of the circulation showed an increase of 7 per cent. "at all ages," the increase being specially marked under five, where it reached 50 per cent., whilst during the school age the figures indicated a reduction of 10 per cent. The increase in the percentage of deaths from these diseases, Dr. Chalmers remarked, had been going on steadily for many years, and was not to be explained by the increasing prevalence of rheumatic disease, a circumstance which he considered suggested that greater attention should be given to the supervision and selection of games and gymnastic exercises. In this direction, as in others, children and young people needed guidance and advice. In conclusion the President claimed that the increased knowledge and improved methods of the sanitarians were already resulting in saving for the nation a large number of lives which under the conditions existing twenty years ago would have been lost. Further, as the deaths were fewer, the disabled also must be fewer, so that our school children now left the arena not only in greater numbers than their predecessors, but the proportion of those among them who were handicapped in the life race by physical disability had been diminished. Credit for this in no small measure was due to the efforts of the educational authorities to provide for the children the conditions of healthy existence and vigorous growth. The address was very cordially received.

Faculty of Physicians and Surgeons, Glasgow.

The following gentlemen, having passed the necessary examinations, have been admitted Fellows of the Faculty: Hugh Galt, M.B., C.M. Glasg., and Clarence Alfred Wright, L.R.C.P. & S. Edin., L.F.P.S. Glasg.

University of Glasgow.

Post-graduate classes in Bacteriology and Practical Pathology are to be conducted during the vacation by Professor Joseph Coats, assisted by Dr. L. R. Sutherland and Dr. Alexander Ferguson, in the Pathological Institute at the Western Infirmary.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Epidemic of Typhoid Fever at Belfast.

THE epidemic of typhoid fever still continues at Belfast and the admissions into the Union Fever Hospital were for the week ending Sept. 10th more in number than in the preceding one. There are now over 400 cases in that hospital. The type of the disease is more severe than it was in the beginning and hæmorrhage and other serious complications are more common. Everyone is waiting for the Public Health Committee to give information as to what they are doing to remedy the present most serious state of affairs and how they propose to attack the most difficult question of the admittedly deplorable sanitary condition of Belfast. It will take an enormous expenditure of money to remedy the defects of the town, but we are sure if the Public Health Committee will only face these difficulties the citizens will give them their unanimous support.

Outbreak of Fever at Markethill.

At a meeting of the Armagh Board of Guardians held on Sept. 6th Mr. Marshall reported that in Markethill, of which he is medical officer of health, there has been since July an outbreak of enteric fever and scarlet fever has also affected a number of persons. Everything is being done by Mr. Marshall to limit the spread of the disease.

Cookstown Sewerage System.

The Cookstown Board of Guardians have decided to apply for a loan of £1370 for the purpose of extending the sewerage system of Cookstown and a special committee has been appointed to discuss various matters regarding the sanitation of that town.

Water Famine at Cushendall.

Dr. Fogarty, the sanitary officer of this beautiful health resort in county Antrim, reported to the Ballycastle Board of Guardians at their meeting on Sept. 10th that the town was practically without water. The question of a water-supply will be fully considered on Sept. 24th.

The Cork Hospital Saturday Collection.

The Committee of the Cork Hospital Saturday Collection

Digitized by Google

held a meeting for the purpose of discussing whether it would be well to have the usual collection this year in view of the comparatively small sum realised last year. Some members pointed out that though the managers of certain hospitals in the city were quite willing to accept the sums apportioned to them, they rendered absolutely no assistance to the committee in organising the collection. It was accordingly suggested that the proper course to pursue would be to drop the collection for one year, and thus forcibly impress upon those concerned the importance of taking more than a passive interest in a movement designed to materially improve the financial condition of the institutions with which they are intimately connected. In the course of the discussion it was mentioned that the year the collection was inaugurated (1892) a sum of £970 was available for distribution and that last year the collection amounted to only £370. No doubt this marked decrease was in great measure due to the fact that last year the "Record Reign Fund" for the hospitals had already appealed to the charitably disposed. But even so nobody could assert that the Hospital Saturday Committee had not just grounds of complaint and it is admitted on all hands that they adopted a judicious course in summoning a meeting of the managers of the various hospitals to confer with them as to the best means of making the collection in future a distinct success. At the following meeting every hospital was well represented, promises of assistance were cheerfully given, the committee was largely increased, and the Countess of Bandon was nominated President. Her ladyship has since intimated her intention of accepting the office and doing all in her power to further a movement which appeals to the sympathies of the community at large.

Invitation to the British Association to hold their Meeting in Cork in the year 1900.

Sir Rowland Blennerhasset, President of the Queen's College, Cork, has suggested the desirability of inviting the British Association to hold their meeting in Cork in the year 1900. The suggestion has been taken up warmly by the city corporation and at a meeting of the medical profession of Cork specially convened a resolution was unanimously adopted urging the Association to accept the invitation and promising on behalf of the medical men of Cork that in case of acceptance every effort would be made to provide for the Association a most enjoyable sojourn in the capital of the south of Ireland.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Changes in the Viscera Produced by the 72 Hours' Bicycle Ride.

AT a meeting of the Academy of Science, held on August 29th, M. Regnault and M. Bianchi read a paper in which they said that on the occasion of the recent bicycle race which lasted for 72 hours they had examined the winner, the man who came in second, and the man who came in fourth. They examined them before the race, directly after it, and during the three following days. From this examination they have drawn the following conclusions: The riders have lost weight, and the size of the viscera, notably of the abdominal viscera, such as the spleen, the liver, and the stomach, have diminished. The subcutaneous fat has also disappeared. These changes are due to the small amount of food taken during the race, to the heat, to the want of sleep, and to the mental strain. The thoracic viscera—namely, the heart and the lungs—have hardly shrunk at all owing to the extra flow of blood through them produced by the hard work. The continual movement of the legs and of the pelvis, together with the bending forward of the body, have pushed up all the abdominal organs, and these in their turn have pushed up the heart and the lungs. The liver, as being most dense, has markedly pushed up the right lung and the pyloric end of the stomach has been pushed up so that the organ assumes a crescent shape, and thus food stays in it for a much longer time than usual. These displacements are very marked. The abdominal organs are raised about 4 centimetres and the heart is pushed up towards the neck from 2 to 5 centimetres. These facts form an explanation of the therapeutic use of the bicycle in various ptoses, pleurisy and too straight a position of the stomach. The heart and other viscera of these three riders were extremely powerful and so they were able to finish their ride; the other riders who had somewhat weaker hearts left off quite early in the race. It would therefore be advisable for race-riders to be examined by a medical man to see whether they are fit to stand the strain of long-distance rides.

The Medical Treatment of Epilepsy.

At the meeting of the Academy of Medicine held on Sept. 6th M. Motet referred to the researches of M. Maurice de Fleury on the medical treatment of epilepsy. His work is well worth particular attention, as the debates at the recent congress held at Angers have brought out the slight success which has attended surgical operations in epileptics. M. Motet laid great stress upon the originality of M. de Fleury's work, especially upon his statement that injections of artificial serum enhanced very considerably the sedative effect of bromide of potash. Two or three injections of the serum caused a dose of two or three grains of bromide to act just as well as the enormous dose hitherto given to epileptics, the fits are not nearly so frequent and the mental condition is greatly improved. This action of the serum appears to be due to the power which it has of relieving arterial tension and acting as a cardiac tonic.

A Quasi Laporte Case.

Paris has been within measurable distance of another Laporte case. A woman died and the medical officer of the Registrar's Department called on to certify the death gave a certificate for burial without hesitation. Two busybody neighbours, however, went to the commissary of police and declared that the woman had died after a useless and dangerous operation which she herself had told them she had undergone some days before her death. The police commissary called in another medical man who said that he could not state the cause of death without a post-mortem examination. The medical man who had attended the patient on asking for information was referred to his colleague who was to make the post-mortem examination. That very day one of the daily papers published a full account of the facts, naturally grossly exaggerated, and added that a warrant was out against the operator. Here, however, is exactly what happened. The patient suffered from metritis and used to visit her medical man daily to have the cervix uteri dressed. This was what she called "her little operation." Some days afterwards she died from cerebral hæmorrhage, hence the romance evolved by her neighbours. It is much to be desired that police officials would not be so ready to listen to accusations, and also that the daily press would not bring in a verdict of "Guilty" upon absolutely insufficient evidence.

Sept. 12th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"Contro il Coltello."

THROUGH her associated working-men's clubs Rome has taken an initiative as laudable as it is opportune. She has organised a "Lega Contro il Coltello" (League against the Knife), the instrument carried in contravention of the law by every peasant and artisan and the medium of the homicides, 4000 and upwards, annually perpetrated in Italy. The latest meeting of the League was held on Sunday, Sept. 11th, when a "Statuto" was compiled embodying the "sense" of previous meetings in a series of final resolutions. Its membership is by this time reinforced by an enormous number of "adhesions," and if, as is more than likely, it becomes the parent of other "Leghe" on similar lines in the provinces Italy will have taken a step long expected of her by contemporary Europe towards clearing her character of the stigma which has hitherto been attached to it for "priority in crimes of blood."

The Tragedy of the Quai Mont Blanc.

"Infelix! utcunque ferent ea facta minores." The pathetic Virgilian line rose to many a lip on learning this latest visitation to a House already all too sorely tried. Whatever its past may have been, the Hapsburg dynasty has illustrated the second half of the nineteenth century by as

Digitized by Google

nobly philanthropic a record as any reigning power can point to. The brothers of the late Empress—the Duke Karl Theodor and his younger brother—are well known in the medical world, the former as an ophthalmic surgeon, the latter as an authority in chest diseases, not only professionally qualified but singularly successful among the very poor of town and country, to whom their advice or treatment are restricted, while the Empress herself, conspicuous in every good work, quite shared the family predilection for charitable institutions, chiefly medical. The wretch Lucchesi could have dealt his baleful cause no more deadly blow than that which robbed humanity of such a benefactress and plunged in grief a family literally redolent of generous impulses and kindly deeds. His latest deliverance is as revoltingly cynical as any of its predecessors. In anticipation of the plea which may be set up for him he writes to a Naples journal—the *Don Marzio*—a warning to Lombroso and the Piedmontese school that their efforts to prove him a *criminel-né* had better be spared as he had all his wits about him in perpetrating the deed he glories in. All the same, I believe his antecedents are in course of investigation to show that he belonged to the class of physically as well as morally "degenerate," and enough has already been ascertained to justify Professor Lombroso in asking for opportunities to give scientific proof to his provisional view of the man's defects, organic and acquired. The study cannot but be an interesting one and must aid the endeavours of those who are pressing upon the Government a more searching examination of candidates for military service and a better inspired system of education than the traditional one which allows the promiscuous association of children in all stages of deficiency, moral and intellectual, doing no good to the mentally imbecile, while corrupting those who are normally developed.

Sept. 13th.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the first examination for the degree of Bachelor of Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in September, the following candidates satisfied the examiners:—

OLD REGULATIONS.

1. *Chemistry with Chemical Physics.*—Arthur Hinckes Bird, L.S.A., St. Mary's Hospital; William Curling Hayward, M.R.C.S., L.R.C.P., Charing-cross Hospital; and Frederick William Woolrabe, L.R.C.P. & S. Edin., L.F.P.S.G., Melbourne University.

NEW REGULATIONS.

1. *Elementary Anatomy and Biology, Chemistry, and Physics.*—*First-class Honours:* James Bowden Waters, College of Medicine, Newcastle-upon-Tyne. *Second-class Honours:* Norman Bryan Walker, College of Medicine, Newcastle-upon-Tyne. *Pass List:* John William Crawford, William Morton Emmerson, and Guy Rowland East, College of Medicine, Newcastle-upon-Tyne; Reginald Moyle, Guy's Hospital; Robert Reid Pirrie, College of Medicine, Newcastle-upon-Tyne; Carl Anders Ryman, St. George's Hospital; Thomas Wilson and Robert Younger, College of Medicine, Newcastle-upon-Tyne.
2. *Chemistry and Physics.*—Thomas Englehart Amyot, College of Medicine, Newcastle-upon-Tyne; Anthony Bourchier Bradford, St. Thomas's Hospital; Clement Harlow Cox, Mason College, Birmingham; Charles Courtenay Gibb and Ralph Stuart Renton, College of Medicine, Newcastle-upon-Tyne; Charles Ravenscroft Stewart, St. George's Hospital; and John Benjamin Thomas, St. Mary's Hospital.
3. *Elementary Anatomy and Biology.*—Frederick George Armstong and John William Cross, College of Medicine, Newcastle-upon-Tyne; Wharram Henry Lamplough, Mason College, Birmingham; John Herbert McDowall, College of Medicine, Newcastle-upon-Tyne; Percy Montgomery Rivaz, St. Bartholomew's Hospital; and Monica Lucien Mary Robertson, London School of Medicine for Women.
4. *Elementary Anatomy, Chemistry, and Physics.*—Thomas Corrie Rutherfoord, St. Thomas's Hospital.
5. *Elementary Anatomy.*—Arthur John Spiller Brandon, St. Thomas's Hospital; Charles Fisher, St. Bartholomew's Hospital; Edward Henry Milner-Moore, St. Mary's Hospital; and John Norman Parrott, St. Mary's Hospital.

PRESENTATION.—On Sept. 6th Mr. G. H. Ward-Humphreys, M.R.C.S. Eng., L.R.C.P. Lond., of Cheltenham, was entertained at dinner at the Queen's Hotel in that town and presented with a silver tea and coffee service and silver tea-tray, designed according to the Louis Quinze period. After dinner the toast "Floreat Cheltonia" was proposed by Mr. Ward-Humphreys in an entertaining speech and responded to by Mr. Agg-Gardner.

STREET HAWKING.—The Manchester City Council at their meeting on Sept. 7th unanimously adopted a report from the Watch Committee upon the question of the regulation of street hawking by children. Powers of this kind exist in Liverpool and are found to work well.

MANCHESTER CHILDREN'S HOSPITAL.—A new ward was opened on Sept. 12th at the Manchester Children's Hospital, Pendlebury. The ward in question was used until recently for the reception of fever cases, but the acquisition by the Manchester Corporation of the Monsall Hospital has enabled the authorities at Pendlebury to utilise the ward for general purposes. The necessary alterations and improvements have cost £800 and the change will entail an increased annual expenditure of £1200.

THE half-yearly meeting of the Bristol General Hospital was held on Sept. 12th, Mr. J. S. Fry being in the chair. The chairman stated that for the first half of 1898 the in-patients numbered 1111 and that the out-patients during the same period had increased from 13,630 to 14,102. Subscriptions had slightly decreased as well as donations. Certain improvements had been made in the internal fitting of the hospital, more especially in the kitchen department. The out-patient department had been remodelled, the cost to a great extent being defrayed by a friend.

THE MIDDLESEX HOSPITAL.—The in- and out-patient departments of the Middlesex Hospital will be re-opened on Monday, Sept. 19th, for the admission of patients. The winter session of the Medical School will commence on Monday, Oct. 3rd, when an address will be delivered by Dr. Arthur Francis Voelcker, at 3 P.M., after which the prizes gained by the students during the past session will be distributed by Sir Elliott Lees, Bart., M.P., and a banquet will be held in the evening at the Café Royal under the presidency of the Right Hon. Sir Ralph Thompson, K.C.B., chairman of the council of the medical school.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL AND THE HUXLEY LECTURE.—The annual dinner of the past and present students of the Charing-cross Hospital Medical School will be held in the Venetian Chamber of the Holborn Restaurant on Thursday, Oct. 6th. The chair will be taken by Dr. William Carter of Liverpool and Professor Virchow will be among the guests. Applications for tickets should be addressed to either of the secretaries, Mr. Donald Naesmyth and Mr. P. L. Daniel, at Charing-cross Hospital. We understand also that the Huxley Lecture by Professor Virchow is to be delivered in the large hall of St. Martin's Town Hall (Monday, Oct. 3rd). There are still a few tickets to be disposed of, early application for which should be made to the Dean, Charing-cross Hospital Medical School, 62, Chandos-street, W.C.

LITERARY INTELLIGENCE.—Mr. Young J. Pentland announces the following: Contributions to Clinical Medicine. By T. McCall Anderson, M.D., F.F.P.S. Glasg., Professor of Clinical Medicine to the Glasgow University; physician to the Glasgow Western Infirmary, &c.—Text-book of Physiology. By British Physiologists. Edited by E. A. Schäfer, F.R.S., Jodrell Professor of Physiology, University College, London. Vol. II.—Diseases of the Heart and Aorta. By G. A. Gibson, M.D., D.Sc., F.R.C.P. Edin., assistant physician to the Royal Infirmary; lecturer on Medicine, School of Medicine, Edinburgh.—The Principles of Treatment. By J. Mitchell Bruce, M.D., F.R.C.P.Lond., physician to, and lecturer on the Practice of Medicine at, Charing-cross Hospital; physician to the Hospital for Consumption, Brompton, London.—The Principles and Practice of Medicine. Designed for the Use of Practitioners and Students of Medicine. By William Osler, M.D., LL.D., F.R.S., F.R.C.P., Professor of Medicine in the Johns Hopkins University; physician-in-chief to the Johns Hopkins Hospital, Baltimore. Third edition.—Lectures on Giddiness and on Hysteria in the Male. By Sir Thomas Grainger Stewart, M.D.Edin., LL.D., physician-in-ordinary to Her Majesty the Queen for Scotland, Professor of the Practice of Physic and of Clinical Medicine in the University of Edinburgh.—Text-book of Medicine. By British Teachers. Edited by G. A. Gibson, M.D., D.Sc., F.R.C.S.Edin., assistant physician to the Royal Infirmary; lecturer on Medicine, School of Medicine, Edinburgh.—The Radical Cure of Hernia, Hydrocele, and Varicocele. By C. B. Lockwood, F.R.C.S.Eng., assistant surgeon and demonstrator of Practical Surgery, St. Bartholomew's Hospital;

Digitized by Google

surgeon to the Great Northern Central Hospital, London.—Manual of Midwifery. By R. Milne Murray, M.B., F.R.C.S. Edin., assistant physician to the Royal Maternity and Simpson Memorial Hospital; lecturer on Midwifery and Diseases of Women, School of Medicine, Edinburgh.—The Journal of Pathology and Bacteriology. Edited by German Sims Woodhead, M.D. Edin., director of the Laboratories of the Royal College of Physicians of London and Surgeons of England. Volume V.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ASHER, A., M.B., C.M. Edin., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, for Caithness, Orkney, and Shetland.

BOND, C. HUBERT, D.Sc., M.D., Ch.M. Edin., has been appointed Senior Assistant Medical Officer to the Heath Asylum (for the County of London), Bexley, Kent.

CHESTNUTT, J., B.A., L.R.C.S., L.R.C.P. Edin., has been appointed Medical Officer for the Howden Union Workhouse and District, East Yorkshire, vice H. Tireman, deceased.

CONNON, M., M.B., C.M. Aberd., has been appointed Medical Officer of Health for the Burgh of Montrose.

CONNOP, A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Brailsford Sanitary District of the Ashbourne Union.

COWIE, GEORGE, M.B., C.M. Aberd., has been appointed Medical Officer for the City-road Workhouse, London.

DALLEWY, J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Wem Rural District Council.

FLETCHER, F. A. C., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer for the Sutton and Steeton Sanitary District of the Keighley Union.

GIBBON, A. H., L.R.C.P., F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Bury Town Council.

HARRIS, F. D., M.B. Lond., L.R.C.P., M.R.C.S., D.P.H., has been re-appointed Medical Officer of Health by the St. Helen's Town Council.

INNES, J. C., L.R.C.S., L.M. Edin., has been re-appointed Medical Officer of Health for the Crawford Sanitary District of the Bakewell Union.

KNOX, J., M.D. Aberd., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for the South Division of the Rural Sanitary District, Bakewell Union.

MACKENZIE, M. T., M.D. Edin., J.P., has been appointed a Medical Referee under the Workmen's Compensation Act (1897) for the Sheriffdom of Inverness, Elgin, and Nairn.

NESBITT, R., L.R.C.P., L.R.C.S. Irel., has been re-appointed Medical Officer of Health by the Sutton-in-Ashfield Urban District Council.

PATERSON, HERBERT J., M.A., M.B. Cantab., F.R.C.S. Eng., has been appointed Assistant Medical Officer for the Hospital of St. Francis, New Kent-road, S.E.

PECK, HERBERT, M.B., C.M. Edin., D.P.H. Camb., has been appointed Medical Officer of Health by the Chesterfield Rural District Council, vice Angus Macintosh, deceased.

ROBERTSON, J. A., M.D., C.M. Glasg., has been re-appointed Medical Officer by the Norman Cross District Council.

SCURFIELD, H., M.D. Edin., C.M., D.P.H. Camb., has been re-appointed Medical Officer of Health for the Borough and Port of Sunderland.

SLEITH, DAVID STUART, A.B., M.B., B.Ch., B.A.O., T.C.D., L.M., has been appointed Assistant Resident Medical Officer for the North Dublin Union.

TURNER, J. A., M.B., C.M. Edin., D.P.H. Camb., has been re-appointed Medical Officer of Health for the Ware Sanitary Rural District.

WILSON, G., M.D., C.M. Edin., D.P.H. Camb., has been re-appointed a Medical Officer by the Warwick Rural District Council.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

BATH GENERAL OR ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer.

BOOTLE BOROUGH HOSPITAL.—Junior House Surgeon. Salary £40 per annum, with board, lodging, washing, &c.

BRADFORD ROYAL INFIRMARY.—Honorary Physician.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-Inn-road, W.C.—House Surgeon. Board and residence provided in the Hospital.

CHELSEA, BROMPTON, and BELGRAVE DISPENSARY, 41, Sloane-square, S.W.—Surgeon.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer. Salary £100 per annum, increasing £10 yearly to £120 per annum, with board, lodging, washing, and attendance.

COUNTY ASYLUM, Shrewsbury.—Junior Assistant Medical Officer for four years. Salary to commence at £100 per annum (and £8 in lieu of beer, &c.), with board, lodging, washing, rising to £120 at the end of two years' service.

CROYDON GENERAL HOSPITAL.—House Surgeon for two years, unmarried. Salary £100, increasing £10 per annum to £120, with board and residence in the hospital.

DOVER HOSPITAL.—House Surgeon, unmarried. Salary commencing at £100, with board and lodging.

GLASGOW EYE INFIRMARY.—Resident Assistant House Surgeon. Salary £50, with apartments and board.

HALIFAX PROVIDENT DISPENSARY.—Medical Officer. Salary to commence at £150 per annum, with house rent, rates, gas, and coals free, or furnished rooms, with other arrangements.

HEREFORD GENERAL INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished rooms, board, washing, gas, coals and attendance.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident House Physicians.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.—Three Senior Clinical Assistants. The first appointment will be for six months, but is renewable at the discretion of the Committee of Management. Also Resident Medical Officer. Salary £50 per annum, with board, residence, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—Resident Medical Superintendent for one year. Salary £105 a year, with board and residence in the hospital.

JOINT COUNTIES ASYLUM, Carmarthen.—Second Assistant Medical Officer. Salary £120 per annum, advancing £10 annually to £140, with board, residence, and washing. £5 per annum in lieu of stimulants.

LONDON COUNTY ASYLUM, Claybury, Woodford-bridge, Essex.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to the Clerk of the Asylums Committee, 21, Whitehall-place, London, S.W.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon. Honorarium at the rate of £50 per annum and board.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Assistant to House Surgeon for six months. Board, lodging, and washing provided. No salary.

NORTHAMPTON GENERAL INFIRMARY.—Junior Assistant House Surgeon for six months. Board, lodging, and washing provided and an honorarium of £10 given conditionally.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—House Physician, House Surgeon, each for six months. Salary at the rate of £50 per annum, with board and residence.

PRESTON ROYAL INFIRMARY.—Assistant House Surgeon. Salary £50 per annum, with board, rooms, washing, &c.

SOUTHPORT INFIRMARY.—Junior House and Visiting Surgeon for six months. Residence, board, and washing provided, and an honorarium at the rate of £30 per annum given.

ST. MARY'S CHILDREN'S HOSPITAL, Plaistow, E.—Assistant Resident Medical Officer for six months. Salary at the rate of £40 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £70 per annum, with board, washing, and residence. Also a Junior Assistant House Surgeon. Salary £2 per mensem, with board, washing, and residence.

SUSSEX COUNTY HOSPITAL, Brighton.—Fourth Resident Medical Officer, unmarried. Salary £30 per annum, with board, washing, and residence in the hospital.

WEST RIDING ASYLUM, Menston, near Leeds.—A Lady recently qualified, or Senior Student to act as Resident Clinical Clerk. Board and residence provided.

Births, Marriages, and Deaths.

BIRTHS.

BLIGH.—On Sept. 7th, at Caterham-valley, Surrey, the wife of William Bligh, M.B., B.S. Lond., of a daughter.

CHAMBERS.—On Sept. 9th, at Beaumont-street, Oxford, the wife of T. Rubery Chambers, L.D.S.R.C.S. Eng., of a daughter.

CONNOR.—On Sept. 6th, at Soho-square, W., the wife of S. Grahame Connor, M.B., of a daughter.

MARRIAGES.

BOYD—BEVERIDGE.—On July 30th, at St. Mary's Church, Addington, Christchurch, N.Z., by the Rev. W. S. Bean, Vicar, Alexander Brooke Boyd, M.A., M.B. Oxon., of Richmond, Nelson, to Margaret Miller, eldest daughter of Thomas Beveridge, of Fendalton, Christchurch, and formerly of Balado, Kinross-shire.

DODGSON—ATWOOD.—On Sept. 12th, at Guston, Kent, George Stanley Dodgson, M.B., B.C., son of Mr. A. Dodgson, of Headingley, Leeds, to Jaquetta Marion, younger daughter of the Rev. George Atwood, Rector of Hinton-cum-Steane, Brackley.

OLIVER—CUFF.—On Sept. 14th, at Shoreditch Tabernacle, Herbert Stedman Oliver, surgeon, of Skinner House, Lydd, Kent, to Lizzie Ridley, fourth daughter of Rev. Wm. Cuff, Amesbury House, Stoke Newington, N.

PATON—BALFOUR.—On Sept. 13th, at Dawyck Private Chapel, Peebles-shire, Diarmid Noel Paton, M.D. Edin., eldest son of Sir Noel Paton, R.S.A., to Agatha Henrietta, eldest daughter of the late Alexander Balfour, of Liverpool.

PETYT—HAMMERTON.—On Sept. 8th, at the Parish Church, Beckenham, Kent, Allan I. Petyt, M.A., M.B., B.C. Cantab., L.S.A. Lond., of Loughton, Lancs, to Kate, second daughter of Thomas Moy Hammerton, "Hollington," Beckenham.

DEATHS.

INKSON.—On Sept. 9th, at Acton, Surgeon-Major-General James Inkson, M.D., A.M.S. (retired), aged 62 years.

KINGSFORD.—On Sept. 13th, at Sunbury-on-Thames, Middlesex, Edward Kingsford, F.R.C.S., aged 81 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898, bound in cloth, gilt lettered, price 18*s*., carriage extra; and Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*., can be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

ALCOHOL AS A WOUND-DRESSING.

MR. PEYTON T. B. BEALE contributes to *The Phonographic Record* a note on the use of alcohol which is worthy of attention. The grounds upon which the practice is based seem reasonable and sound. After the bleeding in a wound has ceased, as Mr. Beale says, "the arterioles near the edges dilate, the edges are therefore very richly supplied with pabulum in the form of blood plasma which exudes through the walls of the capillaries. A few septic organisms gain access; they find plenty of food and multiply very rapidly, so rapidly in fact, that the phagocytes are not able to cope with them, and suppuration is the result." Taking advantage of the well-known property of alcohol to check cell growth and cell division Mr. Beale has used alcohol with excellent results; serous exudation is practically absent and wounds unite rapidly after its use. Methylated alcohol is used and before the wound is closed it is lightly swabbed out with a sponge or cotton wool pledget moistened with the spirit. The sutures having been inserted a piece of double cyanide gauze large enough to overlap the wound 4 in. in every direction is dipped in the alcohol and applied. The dressing is then completed in the usual way with gauze wrung out in 1 in 40 carbolic solution, dry salicylic wool, and the bandage. Mr. Beale has used alcohol for swabbing out abscess cavities and boils, and he describes the healing process as "remarkably rapid after its use." The alcohol, in addition to its action on the capillaries, acts as a mild antiseptic and appears to injure the tissues to the smallest possible extent. At the same time we are warned that none of our usual antiseptic precautions must be omitted.

TUBERCULOUS DISEASE OF THE ANKLE-JOINT.

To the Editors of THE LANCET.

SIRS,—A patient came to live near me with a friend suffering fearful pain in the ankle-joint. She never secured a minute's rest or peace and had not done so for a month. Large doses of opium were useless. The ankle was considerably swollen and was treated with cloths rung out with lead and opium lotion and changed frequently. Her medical adviser gave a family history of tuberculous joint disease in several members of the family who had died from tuberculous disease of joints. This patient was seen by several medical men and by a professor of surgery and they all recommended amputation of the foot. This seemed absolutely necessary to save her life, but the patient wished to have change of air before undergoing the operation. She was thirty years of age and had a family of six, who all seemed healthy and strong.

When I first saw her she was suffering the most acute pain in the ankle and had a feeling as if the part were on fire. Evidently it was of no use to apply local soothing applications, as these had proved useless, therefore we arranged to have cold water running upon the bare ankle continually night and day, with the result that in twenty-four hours the pain and burning sensation had passed away and in a few days the swelling had also gone. The water was now discontinued and the patient was given syrup of hypophosphites in large doses thrice daily and she made an uninterrupted recovery and is now in perfect health.

In several cases of tuberculous disease of the joints I have used this treatment and in every case with success. My plan has been to have a large tin reservoir hung up at the foot of the bed with a small piece of rubber tubing, of the size which is used for feeding bottles, to come from the reservoir on to the diseased joint, and to have waterproofing so arranged as to conduct the water to a vessel under the bed. When things are carefully arranged there is no inconvenience caused by the water. I am, Sirs, yours faithfully,

WM. TIPLADY, L.R.C.P. Edin., &c.

Tow Law, co. Durham, September, 1898.

"WANTED A SCHOOL FOR THE DEAF AND DUMB."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent who asks for the address of a good boarding-school for a deaf and dumb boy, I beg to refer him to the Director, School for the Deaf, 11, Fitzroy-square, under whose care I have great reason to know that he would receive the highest educational advantages, &c. I am, Sirs, yours faithfully,

Parolles-road, Highgate, N. K. LUNN.

To the Editors of THE LANCET.

SIRS,—For the information of your correspondent who is asking for the address of a good boarding-school for a deaf and dumb boy ten years old I beg to send particulars of the West of England Institution for the Deaf and Dumb. The regular charge for private pupils who board with the master and matron and sleep in special dormitories is £50 a year, but the committee have power to vary this if there are special circumstances to warrant it. I shall be happy to supply further particulars if required. I am, Sirs, yours faithfully,

Exeter, Sept. 10th, 1898. T. J. ALLEN, Secretary.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent's query in THE LANCET of Sept. 10th I may mention that a school for the oral education of the deaf is kept by Mr. H. N. Dixon, M.A., at Wickham House, East Park-parade, Northampton. Boarders are also received at the school of the Training College for Teachers of the Deaf, Castlebar-hill, Ealing, W. I am, Sirs, yours faithfully,

Sept. 13th, 1898. S.

THE KINEMATOGRAPH IN MEDICINE.

THE *New York Medical Journal* publishes an article on some suggestions thrown out by M. Marcel Baudouin, the chief editor of the *Gazette Médicale de Paris*, on the uses to which the kinematograph may be put in the study and practice of medicine and surgery. The French writer points to its probable utility in such physiological studies as that of the gait in animals and in man, in medical and surgical diagnosis, especially in cases of disease characterised by abnormality of movement, such as ataxia, congenital luxation of the hip, &c., whether the fundamental disease affects the nervous, the muscular, or the osseous system, and, moreover, in teaching operative surgery. M. Baudouin says that ever since the beginning of the year 1897 he has been intending to employ the apparatus in Professor Terrier's laboratory at the Paris School of Medicine, at first for registering the successive steps in operative procedures, with the particular purpose in view, especially in operations involving the viscera, of demonstrating how far current practice is at variance with what is taught theoretically in the books. He was then going to employ it in the study of operations called rapid. Unfortunately for all these excellent purposes, however, it was found that the fund available for the laboratory did not allow of those first trials.

MUSIC IN THE SOUDAN.

AN amusing story has recently appeared in the papers concerning the new Soudanese military bands. Our excellent allies were much impressed with the British brass bands and proceeded to start one of their own. They managed fairly well and played British tunes without understanding much what they meant. One day a Soudanese died and the regiment and band attended the funeral. The band was on its mettle and when the body came in view began to play, but alas for the fitness of things, the tune selected was "Up I came with my little lot."

THE MEDICAL DIRECTORY.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to draw attention to the great inconvenience caused by the present sectional arrangement of Churchill's Medical Directory, lately increased by cutting out Wales. If I want to find the whereabouts of a medical man I have to turn to *seven* different sections before I can find him. It would be far more convenient to have all names alphabetically arranged together, the initials (nearly always known) being a guide to the name. It is much less trouble to run through an alphabetical list of names than to have to turn about to so many different sections. The more a directory is sectionally divided up the more bulky and less useful it becomes. The universities and medical schools would be much more convenient placed all together than separated.—I am, Sirs, yours faithfully,

SUBSCRIBER OF TWENTY-FIVE YEARS' STANDING.

August 26th, 1898.

*** Wales is not "cut out" but only transferred to a section of its own. We must say, however, that we thought the old arrangement the more convenient.—ED. L.

Verax.—The local authorities first decide upon the appointment of a person or persons "possessing"—we are quoting a clause in the Food and Drugs Acts—"competent knowledge, skill, and experience as analysts of all articles of food and drugs." The appointment is then subject to the approval of the Local Government Board. There is no officially recognised qualification for the post, but we believe the Fellowship of the Institute of Chemistry counts for a great deal and may perhaps at a future time be accepted. Our correspondent might present himself for this diploma (F.I.C.), particulars of which will be furnished him on application to the secretary, Institute of Chemistry, 30, Bloomsbury-square, W.C. Years of laboratory practice would be the only way of "getting the work up" and the only course which would justify the candidate regarding himself as "possessing competent knowledge, skill, and experience."

Subscriber, &c.—The most natural and correct style is simply "Dr. X. Y. Z." Of the other two mentioned by our correspondent "Mr. X. Y. Z., M.D.," is sometimes used, and we see no reason why he should not employ the style "X. Y. Z., M.D.," except that it is not customary, but "Dr. X. Y. Z., M.D.," is quite unnecessary.

Mr. Edward Knight.—We do not fancy that there is any book dealing with popular medicine in the various countries mentioned by our correspondent. But there are various papers and articles scattered throughout journals and magazines. Our correspondent might get the information he desires by applying to the Folk Lore Society.

J. P. Dunelm.—Our correspondent is entitled to announce his change of residence and the circumstances under which it is made. The announcement should be made privately through the post.

X. Y. Z.—The drug recommended for mosquito "bites" was ipecacuanha, either the vinum or the powdered root made into a paste with water or vinegar being applied.

Mr. W. R. James.—We never prescribe. Our correspondent should consult his own medical man.

Mr. R. W. Garrett.—The name mentioned does not appear in the current Medical Register.

T. O. D.—We believe the institution in question is extinct. It is not to be found in the Post Office Directory.

F.—The average number of normal respirations in a healthy adult is from 16 to 20 per minute (Quain's Dictionary).

S. E. H. has omitted to enclose his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

ABSTRACT OF A

Post-Graduate Lecture

ON

THE DIFFERENTIAL DIAGNOSIS OF ABDOMINAL DISEASES IN CHILDREN.

Delivered at the Evelina Hospital for Sick Children on March 23rd, 1898,

BY GEORGE CARPENTER, M.D., M.R.C.P. LOND.,

SENIOR PHYSICIAN TO OUT-PATIENTS AT THE EVELINA HOSPITAL FOR SICK CHILDREN.

AFTER referring to the wide range of the subject of the lecture, which made it difficult to compress the matter within the limits of one hour, Dr. Carpenter stated that he hoped to conveniently concentrate this by discussing and demonstrating the method to which he particularly wished to draw attention — namely, that of rectal exploration as applied chiefly to the diagnosis of abdominal and pelvic disease in children. With reference to this method Dr. Carpenter noted the insufficient recognition by the profession of the valuable information which could be gained from rectal examination, and stated that in his opinion if combined with abdominal palpation it was frequently of great assistance in elucidating cases of difficulty. He then quoted as examples the following cases.

CASE 1.—This was a case of obstinate constipation in a little girl in which after assiduous treatment by drugs rectal examination revealed a tumour growing from the anterior surface of the sacrum which later proved to be a myeloid sarcoma.

CASE 2.—A boy, aged three years, was brought to the out-patient department at the Evelina Hospital suffering from an umbilical fistula. A probe could be passed along the fistula for a short distance and careful abdominal palpation revealed a mass of mesenteric glands of about the size of a tangerine orange, with which the sinus was apparently connected. On rectal examination a mass of about the size of a small pea was felt in the position of the prostate and extending from this there existed a slight enlargement of the seminal vesicles on either side. Using the bimanual method the probe could be passed down to the pea-like enlargement where the sinus ended; passing from the fistula to the mesenteric glands was a cord of about the diameter of a lead pencil and oval in shape; the tumour also felt hard and was obviously composed of a mass of glands. No further abnormality could be detected and the case was undoubtedly one of tuberculosis of the vesiculæ seminales and prostate.

CASE 3.—The patient was a child, aged two years, suffering from whooping-cough and broncho-pneumonia. Abdominal examination revealed a tumour suggestive of tuberculous peritonitis; by the combined rectal and abdominal method a horseshoe kidney could readily be detected. This diagnosis was confirmed at the necropsy.

CASE 4.—A boy, aged seven years, a patient under the care of Mr. Lacy of Sunninghill, Ascot, suffered from an indefinite febrile complaint characterised by tumid abdomen, constipation, and ill-health. Typhoid fever was suspected. Nine weeks later, considerable improvement having meanwhile occurred, the patient's temperature suddenly rose to 104° F. and kept at about this point. A rectal examination was made and an abscess was found at the back of the rectum containing about an ounce of foul-smelling pus.

Dr. Carpenter then made reference to the tumour frequently felt *per rectum* in intussusception, which gives a sensation to the finger similar to that obtained from the os uteri in advanced pregnancy, and to the blood-staining of the finger on examination. He afterwards noticed the frequency with which rectal exploration was of service in the diagnosis of tuberculous peritonitis from chronic gastro-intestinal catarrh with loss of muscular tone; if peritonitis were not present, between one finger in the rectum and the other hand on the abdomen the thickness of the abdominal wall only would be felt, whereas if an appreciable quantity of extraneous tissue existed it would point to the existence of lymph and thickening of the peritoneum, whilst intestinal matting and glandular enlargement could in many cases be readily detected.

Dr. Carpenter next considered the pelvic organs in female children. He stated that in a child the sacrum is almost straight and consequently also the rectum, that the bladder is egg-shaped with the larger end downwards, and is almost entirely an abdominal organ, and that the uterus consists almost entirely of cervix and is readily felt by rolling it between the finger and the symphysis pubis. He then noted that if the finger be introduced for a short distance into the rectum the sharp edges of the falciform ligament can be readily recognised, forming a sickle-shaped curve surrounding the rectum and attached behind to the sacrum, and in front to the lower part of the cervix; that guided by this structure the tubes and ovaries could be readily manipulated between the examining finger and either the bony wall of the pelvis or more frequently the tips of the fingers of the other hand placed on the lower part of the abdomen, and, finally, that at this stage the uterus could be examined. As an example of the normal size of the pelvic organs Dr. Carpenter stated that in a child, aged two years and four months, the uterus is 1 in. in length and ½ in. in breadth at the fundus; the tubes are 1¾ in. in length; and the ovaries ½ in. in length and ⅛ in. in diameter. He next referred to various pathological conditions which can be detected. Small cysts of the ovary cannot infrequently be felt and displacements of the ovaries and tubes into the inguinal and crural openings can be demonstrated. Tuberculous disease of the uterus, tubes, or ovaries is exceedingly rare in children, but several cases of this were quoted and many drawings were exhibited. Inflammatory diseases of the ovaries and tubes have not received much attention up to the present time. Sanger,[1] however, of Leipsic, records the case of a little girl who contracted gonorrhœa and subsequently developed all the symptoms of acute pelvic peritonitis. Marx[2] also points out that salpingo-oöphoritis sometimes complicates vulvo-vaginitis in infants, the symptoms being similar to those found in adults. He refers to 15 post-mortem examinations on cases which exhibited symptoms of this complication, and in 5 of these he found that the Fallopian tubes contained pus and had their uterine attachments sealed. He states that these uterine inflammatory conditions may become exacerbated at puberty and may cause inflammatory pelvic conditions in newly married women. In a patient under the care of Dr. Carpenter, aged twenty-two months, and suffering from congenital syphilis, a tumour could be detected in the right inguinal region of the size of a French walnut; on rectal examination the uterus was found to be normal and attached to its upper part, by a short, cord-like enlargement, was the tumour, on the posterior surface of which could be felt what appeared to be a convoluted tube. The tumour was freely moveable and on bimanual examination fluctuation could be obtained in it. The ovary of the opposite side was normal, but on the affected side it could not be found. The liver and spleen were both enlarged. Pyosalpinx or possibly tubo-ovarian cyst was diagnosed and the case was successfully operated upon. The tumour contained foul-smelling pus and was probably a suppurating ovarian cyst burrowing between the layers of the broad ligament.

The earliest ovariotomy on record was successfully performed by Roemer, the patient being one year and nine months old. Dr. Carpenter has collected from gynæcological literature 35 cases of ovariotomy performed on patients of twelve years of age and under: of these 15 were dermoids, 10 cystic tumours, 6 sarcoma, 2 carcinoma 1 malignant tumour, 1 cylindro-epithelioma, and 1 fibromyoma. Rosenstein has reported a case of carcino-sarcoma in a child aged two years and Ganghofner a case of carcinoma of the uterus in a child eight years of age. 20 cases of carcinoma of the vagina under twelve years of age are recorded; they commonly exist as multiple polypi, do not usually ulcerate, run a chronic course, and end fatally, the surrounding organs and tissues being occasionally attacked.

Dr. Carpenter then spoke at some length on the subject of tuberculous peritonitis. He grouped this disease under the following clinical headings:—

1. A matted condition of the bowel associated with

[1] Keating's Cyclopædia of Diseases of Children, vol. iii., p. 739.
[2] Gazette de Gynécologie, Nov. 15th, 1895.

Digitized by Google

tuberculous ulceration and caseous disease of the mesenteric glands and exhibiting the symptoms of the so-called tabes mesenterica.

2. A tuberculous condition characterised by the existence in the abdomen of hard and fixed masses usually lying close under the parietes and due to the luxuriant growth of miliary tubercle. This if occurring in the omentum causes it to become thickened and contracted into a band or plate stretching horizontally across the upper part of the abdomen, or at other times the result is the formation of a thick apron lying in front of the intestines and adherent to them and to the liver, spleen, and parietes. A mass may also form in Douglas's pouch and be detected on rectal examination. Again, isolated masses, usually composed of intestinal coils matted together with tuberculous deposit outside the bowel, may give rise to a somewhat puzzling physical sign—namely, a frequent variation in the size and definition of the masses. Finally, a large mass or plate may exist between the liver and diaphragm in such a position as to be clinically unrecognisable. Very exceptionally these fixed lumps may be due to caseation of the mesenteric glands alone and it may be noted as an important fact that advanced caseation, fibroid change, or calcareous degeneration may exist in a mass of glands large enough to form an abdominal tumour with either a relatively small amount of intestinal ulceration or a mere injection of the mucous membrane. Neither fever nor ascites is a marked feature in these cases, though either may occur, and this class of cases as a rule enters the wards of a hospital, not owing to the abdominal condition, but as cases of tuberculous meningitis, of lung disease, or of extreme asthenia associated with diarrhœa. Sometimes, of course, the condition is diagnosed during life, but probably more frequently the fact is first brought to light at the necropsy owing to more prominent and striking symptoms having during life engaged the attention of the observer. In a girl, aged ten years, a fixed tumour existing in the abdomen was due to the following morbid changes which were limited to the last two feet of the small intestine. Here and there in this region to within six inches of the ileo-cæcal valve there was extensive ulceration associated with caseation and matting of the neighbouring glands, the whole being bound together by dense adhesions. Some of the ulcers were of cartilaginous hardness; the rest of the abdominal cavity was free from disease. There was secondary tuberculous pulmonary implication. The limited extent of the disease in this case suggests the possibility of its having started in a mild attack of enteric fever. A general impression seems to exist that the majority of cases of this type ultimately recover, but this seems not to be the case. In many instances, in addition to the tuberculous masses, caseation of the mesenteric glands and intestinal ulceration are present; these are the worst class of cases and border on the group enumerated under Heading 1.

3. Under this heading are placed cases which come under observation suffering from ascites; this may be the only condition existing throughout the illness, though perhaps a rectal examination may reveal some slight thickening of the abdominal contents. Ascites may hide the existence of such tuberculous tumours as have been described under Heading 2, and these may only be detected after paracentesis or if the fluid becomes absorbed. Miliary tuberculosis of the peritoneum may give rise to a considerable collection of fluid or, on the other hand, to a quantity too small for detection by clinical methods. Tubercles, again, may be found in considerable numbers in the peritoneum without the existence of any inflammatory symptoms whatever. Very little fever usually exists in these cases. The temperature may be raised for a day or two to 100° or 101° F., but it usually quickly falls to normal. On the other hand, a hectic type of temperature may exist for a considerable period in cases which ultimately recover.

4. The cases which come under notice as abdominal abscesses, but which ultimately prove to be tuberculous in nature.

5. Cases exhibiting few definite physical signs beyond an enlarged and tympanitic condition of the abdomen. There may be some variety or other of diarrhœa, the stools may have a typical pea-soup appearance or may be loose and contain masses of a putty-like consistence or a larger or smaller amount of white, flaky material or even obvious particles of undigested food. Such a case may at one moment from the associated signs and symptoms be thought to be one of typhoid fever and at another to be merely one of intestinal disturbance from improper feeding. In this group of cases no gross lesions exist and a rectal exploration may prove of the utmost assistance in enabling the observer to form an opinion on the subject of peritoneal implication.

Dr. Carpenter then referred to certain conditions liable to be mistaken for tuberculous peritonitis, such as fæcal masses, malignant disease, or even tumours due to simple inflammation of the peritoneum. Masses of scybala are usually situated in the right hypochondrium and left iliac region and are due to fæcal accumulations in the region of the hepatic or sigmoid flexure. They may be recognised by their irregular shape, by the possibility of moulding them by manipulation and by their removal by enemata. With reference to simple inflammation of the peritoneum Dr. Carpenter quoted the case of a male infant, aged eleven months, who had suffered for 14 days from severe paroxysmal pains in the abdomen accompanied by nausea and vomiting; he was pale but fairly nourished. The abdomen was distended and prominent. Around the umbilicus was a well-marked local projection which was reddened, tender to the touch and considerably indurated. There was dulness in the left umbilical, hypogastric, inguinal, and lumbar regions, but no fluctuation. A fortnight later a fæcal fistula formed near the navel and soon large, loose, yellowish motions, mixed with pus, were passed through the wound. A week later he died from exhaustion. At the necropsy a large abscess cavity existed filled with yellow semi-solid fæcal material, on the removal of which a greyish wall was visible covered with flakes of shreddy lymph. Beneath this lay many coils of intestine matted together. A fistulous opening existed at the upper end of the ileum, and the mucous membrane surrounding the opening and in other parts of the bowel was quite healthy; hence probably in this case the local peritoneal abscess opened into the bowel and did not originate in an intestinal perforation. Dr. Carpenter then referred to the subject of enlarged spleen and demonstrated a number of cases. He stated that in most cases a chronic enlargement of the spleen in children indicated syphilis, rickets, a disease of unknown causation associated with changes in the blood, or tubercle. With regard to the diagnosis of tubercle both in the abdomen and in other parts of the body Dr. Carpenter stated that he had been frequently aided in doubtful cases by an ophthalmoscopic examination of the fundus oculi. He remarked that in his experience tubercles in the choroid were not, as many have thought, so rarely met with or so hopeless to discover as the proverbial needle in the haystack. On the contrary, he had found the routine and careful use of the ophthalmoscope of the greatest value in the elucidation of difficult cases. Several cases were described as illustrations of this fact, and of these the following one is particularly instructive. For six weeks a boy, aged eight years, with a family history of tubercle, had been attended for gastric disturbance. During this time his temperature had been irregular, never above 102·4° F., and at times the morning temperature was in excess of that in the evening. At this time he was dull and apathetic. The only abnormality to be detected apart from extrapuerile breath-sounds was an enlarged mesenteric gland of the size of a hazel nut to the left of and slightly above the umbilicus. On ophthalmoscopic examination of the left eye by the indirect method the optic disc was found to be normal, but when the eye was directed to the right a round fawn-coloured tubercle of the apparent diameter of a No. 1 shot could be seen close to a retinal vein, and passing across its surface was a tiny offshoot from the vein. In the case of the right eye the optic disc was again normal, but when the eye was directed down three similar fawn-coloured tubercles were noticed in the choroid. An unfavourable prognosis was consequently made and this was justified by the result, the patient dying a few days later.

Dr. Carpenter concluded his lecture by briefly describing the appearances seen in tubercle of the choroid. The tubercles are exceedingly protean in their characteristics. They present all shades of colouration, from paper whiteness to grey and yellowish-white, or from yellowish-grey to a fawn colour. Sometimes a shimmering white central spot is seen. In shape they may be circular, oval, triangular, reniform, or quadrangular. They may be clearly cut or blurred, as may also be the retinal vessels in their immediate neighbourhood. They are not necessarily situated in the neighbourhood of the optic disc, but may be detected even at the periphery of the fundus.

[After the lecture numerous drawings of the ophthalmoscopic appearances seen in tubercle of the choroid were exhibited.]

GASTRIC TETANY.

BY E. F. TREVELYAN, B.Sc., M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE LEEDS GENERAL INFIRMARY; PROFESSOR OF PATHOLOGY IN THE YORKSHIRE COLLEGE (VICTORIA UNIVERSITY).

TETANY complicating gastric dilatation is admittedly a rare disease, only some 45 cases having been recorded, yet 2 such cases have been received into the Leeds General Infirmary within a period of little over a year. Details will be given first of a case in which the gastrectasis was the result of a duodenal carcinoma, which is itself also a rare affection. Some remarks will then be made on this case in the light of such records of published cases of gastric tetany as are within my reach. Under the morbid anatomy the outlines, unfortunately very imperfect, will be given of a second case in which the dilatation was due to causes acting outside the stomach and duodenum. A few observations will then be made upon the pathogeny of this form of tetany and on the occasional association of tetany and renal disease, including albuminuria. Finally, the possible occurrence of tetany in gastric disease other than dilatation, with an illustrative case, will be referred to and some points in duodenal carcinoma will be mentioned. I am indebted to the house physician of the Leeds Infirmary, Mr. Hirst, for notes of the first case, and to Dr. Roberts, the resident medical officer, for notes and a photograph of the second case and for the post-mortem reports of both cases.

CASE 1.—A woman, aged forty-five years, was admitted into the Leeds General Infirmary on July 5th, 1898, suffering from vomiting and loss of flesh. Many years before she had suffered from anæmia and fifteen years ago she had had hæmoptysis. She had been much troubled with indigestion, but had never vomited blood. The patient was in her ordinary somewhat weakly health up to a month before her admission, when she began to suffer from a dragging pain in the region of the stomach which was worse after food. A week later severe vomiting supervened and almost everything she ate was vomited and she was therefore compelled to limit herself to a liquid diet. During the week previous to her admission she had had cramps in her legs which came on after excessive vomiting. The following note was made as to her state when she was admitted: "The patient is a spare woman, weighing 6 st. 12 lb. She shows signs of much wasting. There is no vomiting or pain at present. The temperature is 98·4° F., the pulse is 84, and the respirations are 20. The tongue is coated and the bowels are constipated. She feels very hungry. In the abdomen there is a marked prominence occupying the umbilical region obviously due to the dilated stomach. The lesser curvature is clearly visible above the umbilicus and the greater curvature 1½ in. below it. The prominence extends 2½ in. to the right of the middle line. Peristalsis can be distinctly seen, the wave passing from left to right." It was thought that a tumour could be felt over the right extremity of the dilated stomach about 2½ in. to the right of the middle line and 1½ in. below the costal margin. The urine contained a trace of albumin, but the other organs presented no evidence of disease. There was no vomiting from the evening of July 4th up to the evening of July 6th and the patient felt quite comfortable and took small quantities of solid food. On the evening of July 7th copious vomiting again appeared and persisted during the night. The next morning tetany supervened without any previous tingling in the extremities. The hands and arms were chiefly affected with the painful tonic spasm. The fingers and thumbs assumed the position described as the "obstetric hand" and the wrist and elbows were flexed. The feet were also involved and she lay propped up in bed with flexed knees. The muscles of the jaws were somewhat rigid and there was difficulty in opening the jaws at all widely, but the speech was unaffected. The patient was much exhausted, her face was dusky, her lips were blue, and her pulse was small. The temperature was 94·6°. An attempt to wash out the stomach was abandoned. I saw the patient at 2 P.M. on July 8th, when the tetany was still present though the vomiting had ceased. The stomach was emptied and thoroughly washed out with saline solution. A nutrient enema was given at once and a hot rectal saline injection ordered to be given in two hours. She improved, but only temporarily, and died a couple of hours later from exhaustion. Death was preceded by a more generalised spasm.

Necropsy.—The body was that of a much wasted woman. There was no jaundice. When the abdomen was opened the stomach was seen to be enormously dilated, the greater curvature extending down to the pelvis. No growth could be seen, but a mass of the size of a walnut was felt in the neighbourhood of the duodenum. When the stomach and duodenum were laid open the growth was seen to extend from just above the papilla downwards for 1½ in. It seemed to almost completely obstruct the lumen of the gut. Although the papilla was surrounded by growth, yet there was no obstruction to the common bile-duct, for bile could be readily expressed from the gall-bladder into the duodenum. The growth extended through the whole intestinal wall and two or three small and more recent nodules were present in the pancreas. The microscope showed the tumour to be a cuboidal-celled carcinoma containing much fibrous tissue. The stomach was dilated and its walls were thickened. The pylorus was healthy but dilated. The kidneys were small and cirrhotic and presented a typical red granular appearance. With the exception of pleural adhesions all the other organs to the naked eye appeared to be healthy.

Although the clinical examination was deficient in certain details, especially in regard to the symptoms of Trousseau, Chvostek and Erb respectively, the diagnosis in this case cannot, I think, be doubted. It has been urged that all cases of tonic spasm occurring in dilatation of the stomach are not to be called tetany. So distinguished an authority on tetany as Frankl Hochwart[1] writing in 1897 only recognises as genuine gastric tetany 11 out of some 40 cases reported up to that time. The grounds, however, on which some of the cases have been excluded are not always obvious. The advantages of distinguishing between gastric tetany and gastric dilatation with tetanoid spasm are not altogether apparent unless it can be shown that the two conditions differ in cause as well as in symptoms. It certainly seems convenient to include under the name of gastric tetany, as most writers do, at least all cases of gastric dilatation complicated with such tonic spasm in the extremities as is seen in ordinary tetany. If the classification given in Bouveret and Devic's[2] paper be accepted, the above recorded case would fall into the second group, where the spasm of the extremities is also accompanied by tonic spasm in the muscles of the face and neck or trunk. The rapidity with which death may occur in this disease is well illustrated by this case. In Marten's[3] case the single attack of tetany proved fatal in four hours. In a very few instances (Müller,[4] Kussmaul[5]) a long interval of comparative health had separated previous attacks of tetany from the fatal one. Although in the case now recorded there had been dyspeptic symptoms for many years, yet the gastric dilatation leading to the tetany had probably not existed more than a few weeks. The reason that dyspeptic symptoms have usually been noted for many years previously is because by far the most frequent cause of gastrectasis complicated by tetany is cicatrisation of an ulcer. Severe vomiting has been almost a constant precursor of gastric tetany and has been immediately preceded by tingling in the extremities. The vomiting, but not the tingling, was present in this case. Albuminuria was noted here as in several other recorded cases. There was no particular thirst. The temperature fell during the attack to 96·4°. Often a rise and not a fall of temperature has been noted; in Collier's[6] cases it reached 109° before death. The patient resembled in many respects one dying from acute abdominal disease, consciousness being maintained to the end. The embarrassment of respiration so frequently observed in gastric tetany was absent.

There are one or two facts which stand out in much prominence when the morbid anatomy of gastric dilatation fatal by tetany is considered. In by far the large majority of the cases, as mentioned above, the gastrectasis has been the result of the cicatrisation of an ulcer or very rarely, as in the cases of Bouveret and Devic,[7] Richartz,[8] and Riegel,[9] carcinoma has developed in the simple ulcer. Attention has

been drawn by more than one writer to the comparative frequency with which a duodenal ulcer has been found in gastric tetany such as in the cases recorded by Bamberger,[10] Dujardin-Beaumetz,[11] and Renvers.[12] More frequently still the pyloric ulcer has extended into the duodenum (Neumann,[13] Loeb,[14] Müller,[15] Thiroloix and du Pasquin [16]). There seems to be no explanation forthcoming of why, considering their infrequency, these duodenal ulcers should lead relatively often to gastric tetany. In another group of cases the cause leading to obstruction of the duodenum has operated from without. A very remarkable case was recorded by Blazicek [17] in which the gastric dilatation was due to the pressure upon the duodenum of a thickened and calculus-containing gall-bladder. In one of Müller's [18] cases there was an hour-glass contraction of the stomach due to past gastric ulceration with an axial rotation which had led to closure of the duodenum. In Berlizheimer's [19] case a pancreatic cyst had pressed on the duodenum. I may now refer to another case of gastric tetany in the Leeds General Infirmary, under the care of Dr. Barrs, who has kindly allowed me to make use of it.

CASE 2.—A woman, aged sixty years, was admitted into the infirmary on July 3rd, 1897, with gastric symptoms. The outlines of the greatly dilated stomach were distinctly visible through the abdominal walls and there was incessant vomiting. On the evening of July 4th she developed tetany, the hands and arms assuming the characteristic position of that disease. There was much pain in the arms and legs. She died in a few hours and consciousness was preserved until the end. The temperature rose to 100·4° F. before death.

Necropsy.—The body was considerably emaciated. When the abdomen was opened the stomach was seen to be greatly dilated and reaching far below the umbilicus. The stomach being laid open, the upper part of the duodenum was seen also to be dilated, but there was no trace of cicatrised ulcer or other lesion. There was a mass of new growth occupying the middle of the body of the pancreas, but the head was quite free from disease. There was also a small mass of growth (primary carcinoma) in connexion with one ovary. There was no peritonitis. The kidneys were distinctly diseased. The right kidney was small and weighed only 3¼ oz., whereas the left kidney was enlarged and weighed 6¼ oz. Both presented undoubted evidence of cirrhosis. I may add that I have recently carefully examined the stomach and duodenum, including the head of the pancreas, and I could find no lesion which would account for the gastric dilatation. There was some evidence of past adhesion about the duodenum.

This case is interesting from two points of view—namely, (1) the entire absence of any disease of the stomach itself or duodenum to account for the gastric dilatation and (2) the presence of renal disease. The dilatation could not have been due to the malignant disease of the pancreas, for the head of this organ was quite healthy. I am inclined to think that it was caused by an anchoring of the pylorus or duodenum through adhesions. In the case reported by Holman [20] the stomach was much dilated, but there was also no sign of ulceration past or present. In de Beaurmann's case quoted by Fenwick [21] the dilatation is said to have been atonic. Singer [22] in the Vienna Medical Club stated that dilatation of the stomach is not always present in cases of gastric tetany, but often only an atony; no cases are given in support of this view. In Merlin's [23] case quoted by Sievers there were dilatation of the stomach and hæmorrhages and erosions in the mucous membrane of the stomach and duodenum.

It has been very properly suggested that any satisfactory explanation of the etiology of gastric tetany must take cognisance of the frequent occurrence of ulcers wholly or partially cicatrised. Bouveret and Devic [24] thought they had discovered the connecting link in the hyperchlorhydria frequently associated with gastric ulcer. Excess of hydrochloric acid has certainly also been found in gastric tetany by Gumprecht [25] and Thiroloix and Du Pasquin.[26] The occurrence of tetany in gastric carcinoma developing in an old gastric ulcer would not militate against this view because hyperchlorhydria has been known to occur in this small subgroup of gastric carcinomata. On the other hand, there are cases of gastric tetany on record in which free hydrochloric acid has been absent from the gastric contents, as in Blazicek's [27] case. In addition, there are cases referred to above in which pressure from without and other conditions presumably unassociated with gastric hypersecretion have led to dilatation of the stomach and tetany. Thus, if Bouveret and Devic's [28] views are correct as regards some cases they certainly are not so for all.

Of the three or more theories put forward to explain the origin of gastric tetany the auto-intoxication theory has very rightly found the widest acceptance. Neither the loss of fluid to the body, first put forward by Kussmaul but afterwards disclaimed by him, nor yet the reflex theory supported by G. Sée, Müller,[29] Berlizheimer,[30] and others, offers a satisfactory explanation. Fleiner, quoted by Max Einhorn,[31] has warmly supported the first-named theory, but Blazicek [32] showed by actual investigation that in his case, at all events, there was no increased loss of water to the blood. Jürgensen,[33] however, in commenting quite recently upon a case of cerebral symptoms with clonic convulsions occurring in gastric dilatation also leans to this view. Another very strong reason against it is the fact that there are not a few pathological conditions in which either adequate fluids are not supplied to the body or excess of fluids are drained away from it without producing tetany.

With increasing knowledge the application of the reflex theory to the actual causation of disease has gradually been narrowed down within very modest limits. It is true that gastric tetany has followed almost immediately on passing a stomach tube (Fenwick,[34] Collier,[35] and others), or on percussion or even stroking the abdomen (Müller [36] and Gerhardt [37]), yet, as Loeb [38] and others have pointed out, it would be equally reasonable to attribute ordinary tetanus to reflex causes, since such peripheral irritation will suffice here also to bring on the paroxysm of spasm. The presence of entozoa in the intestine in cases of tetany such as the one described by Riegel [39] and others and the disappearance of the disease with the evacuation of the parasite have been looked upon by some as being evidence in favour of this reflex view. Yet it is not impossible that these parasites themselves lead to the development of poisons, a view lately discussed by Peiper.[40] If the auto-intoxication theory be accepted it is an easy matter to believe that the same convulsive poison which produces the tetanoid spasm also heightens the excitability of the nervous centres, so that a slight peripheral irritation may suffice to call forth the spasm. In support of the intoxication theory Bouveret and Devic [41] have separated from the stomach contents of a patient with permanent hyperchlorhydria a poison soluble in alcohol which produced convulsions in animals. They thought that this poison arising in the stagnate and hyperacid gastric contents in dilatation of the stomach would explain this form of tetany. On the other hand, cases have been examined with negative results by very reliable observers, such, for instance, as a case by von Jaksch and Berlizheimer,[42] one by Blazicek [43] assisted by Landsteiner, and also Müller's [44] cases. Fleiner, quoted by Gumprecht,[45] obtained positive results in his case only after a certain chemical treatment of the gastric contents. Gumprecht's elaborate investigation also gave a somewhat uncertain result. The alcoholic precipitate containing albumoses and salts possessed marked toxic properties, but the albumoses had not been absorbed, since there were none present in the urine. This

observer concludes that in his case the presence in the body of any special poison at the time of the tetany, such as might be looked upon as the basis of an auto-intoxication, could not be proved by the ordinary methods. If a poison is manufactured in the abnormal chemical processes in the dilated stomach its absorption should lead to a greater urotoxic coefficient and also it should be possible to separate this poison from the urine. Gumprecht found a higher urotoxic coefficient in his case, but it was present both in the interval as well as during the attack, and Jacobson and Ewald [40] obtained from the urine of their case a ptomaine-like body. There have been other investigations in tetany, notably by Albu, to which I have not referred, as my object is merely to roughly indicate the present position of the subject. Unfortunately no investigations of any kind were made in my cases. However, plausible and probable the auto-intoxication theory is, it cannot as yet be looked upon as having been definitely established by experiment.

There is, however, another point of considerable interest also connected with the intoxication theory in the relation of gastric tetany to renal disease including albuminuria, In not a few cases of gastric tetany (Loeb,[47] Merlin,[48] Dreyfuss Brisac,[49] Blazicek,[50] Galliard,[51] Fenwick,[52] Sievers[53]), albuminuria has been noted. In some of these cases the kidneys have been found healthy after death, at least so far as the naked-eye appearances were concerned. Poisons excreted by the kidneys, whether in the infections or the intoxications, may, and frequently do, injure the kidney in their passage through it. I have not met with any particular researches into this subject in tetany, gastric or other. In one of Hoffmann's [54] cases of tetany (No. 6) it is stated that there was an acute nephritis, but no exact details are given. The relation of tetany to chronic nephritis is perhaps of greater importance. In one of Blazicek's cases and in both of mine there was more or less advanced renal disease. Wick [55] has related a case of tetany, not of gastric origin, in a patient who was the subject of granular kidney, but, as Frankl Hochwart [56] points out, there are so many factors present in this case that it is difficult to interpret it. In No. 7 of Hoffmann's [57] cases, in a lad aged nineteen years, there was also chronic nephritis, but in the reading through the details of the case the question arises whether it might not be a mere matter of coincidence. It has not been proved that the poison or poisons causing uræmia can set up the spasm of tetany nor clinically is there any reason to suspect such a possibility. There is, however, another aspect of the relationship of tetany and renal disease. If tetany is due to a poison excreted by the kidneys then anything which would render the kidneys less efficient excretory organs should precipitate the attack of tetany. It may be, as Bouveret [58] says, that a sudden augmentation of the poison or a temporary insufficiency in the elimination may determine the attack, but this view as yet quite lacks the necessary proof. Before leaving the kidneys it may be mentioned that acetone, to which, indeed, Biscaldi [59] attributed the tetany in his case, and also sugar (Fenwick [60] and others) have been found in the urine. Frankl Hochwart [61] has specially drawn attention to the question of season and tetany, and Gumprecht [62] says that 75 per cent. of the cases of gastric tetany occur from January to March, the months in which ordinary tetany is most common. The figures as regards gastric tetany are certainly too small to base any conclusions upon. Both my cases occurred in July. Of Sievers's [63] cases recently published one occurred in April and the other in November, and of the other two cases referred to in his paper Holstoi's was noted in February and Bockman's in April. The greatest frequency of tetany at a given time of the year, epidemic outbreaks of the disease, its occurrence as a complication of infective illnesses, the frequent rise of temperature noted and other facts, have been appealed to in support of an infective origin.

A question of some importance arises as to whether tetany may occur in connexion with gastric disease other than dilatation. Max Einhorn [64] and some other writers accept this view. Schlesinger [65] in the Vienna Medical Club reported a case in a woman, aged thirty-five years, which occurred in connexion with an acute gastro-enteritis caused by eating contaminated sausage. The same writer drew attention to an almost unknown form of tetany which he described as chronic benign tetany of gastric origin. Perhaps the following case, which Dr. Barrs has very kindly placed at my disposal, falls into this category.

CASE 3.—A girl, aged seventeen years, a patient under the care of Dr. Cheetham of Guiseley, complained of cramps in the hands and feet. When she was seen by Dr. Barrs the hands presented the typical position found in tetany. The tonic spasm also affected the legs. It was stated that the face was involved at times. The attacks came on chiefly in the afternoon and lasted until night and were preceded by vomiting. The patient was a delicate girl and diarrhœa and vomiting were very readily induced. There was no evidence of gastric dilatation. The girl's parents stated that the attacks had recurred on and off for six years, but that during the last two years there had been no recurrence. They were certain about the relation of the spasm to the vomiting; indeed, they attributed the spasm to the vomiting. Beyond being worse in cold weather the parents could give no information about the relation of the attacks of tetany to any particular months in the year. The patient is now perfectly well.

The chief interest in this case is the systematic occurrence of the attacks of tetany after severe vomiting. It is this fact, together with the long period of time over which the attacks were observed, which separates the case from ordinary tetany. Of course, gastro-intestinal symptoms are not uncommon in tetany of children, but the regular association of the vomiting and tetany is, I take it, a different matter. I may mention here that tetany is decidedly an uncommon disease in Leeds and its neighbourhood.

The diagnosis of gastric tetany is mostly quite easy. Fenwick,[66] however, tells of a case in which apparently there was some chance of mistaking the disease for uræmia and in my first case the idea of uræmia presented itself but was easily set aside. If the term "gastric tetany" is allowed to include the milder as well as the severer cases, and there is no sufficient reason against this view, then the disease may turn out to be more common than is usually supposed. The transition between gastric tetany strictly so-called, tetany with gastro-intestinal symptoms, and ordinary tetany would seem to be a gradual one. The prognosis of tetany occurring in gastric dilatation is undoubtedly very serious; nearly 75 per cent. of the cases die. The largest mortality occurs in the groups 2 and 3 referred to above, that is, where the spasm in the extremities is associated with tonic spasm in the head and trunk muscles or with clonic spasm. If the very strict views are held as to the disease then the outlook is almost hopeless; thus of the 11 cases recognised by Frankl Hochwart only 1 recovered. There is a danger here, as in some other diseases, that the fatal issue is raised to be the chief criterion as to the nature of the affection.

After what has been said under the prognosis it may be thought that little need be added about the treatment of gastric tetany, yet in some cases, and notably one by Blazicek, [67] the fatal issue was warded off for a time by systematically washing out the stomach. On the other hand, as mentioned above, the tetany itself has been ascribed to the stomach-tube, and undoubtedly the paroxysm has sometimes followed almost immediately upon its use. Some time ago this fact so impressed itself upon some observers, such as Fenwick, [68] that the opinion was expressed against washing out the stomach in this disease. Most writers, however, including Fenwick, now agree that this method of treatment should be adopted. With the soft tube now in general use the risk of provoking an attack should be reduced to a minimum. Before the stomach is emptied it is perhaps well to supply fluid to the body in the form of saline injections into the rectum or subcutaneous infusion. In my case the stomach was thoroughly washed out, sterilised saline solution being used for the purpose as soon as the wash-water became clear. In some quarters it has been strongly stated, perhaps rather from theoretical considerations, that alcohol should be avoided in gastric

dilatation. Other authorities have, perhaps, more correctly stated it when they say that alcohol should be avoided if it is found in the stomach some time after it has been taken. Penzoldt[69] says that the treatment should aim chiefly at avoiding the occurrence of this fatal disease. He draws attention to the fact that Boas recommends diuresis. Rectal injections of milk are also mentioned by Penzoldt, otherwise the treatment is symptomatic. If the tetany ceases and the general condition of the patient permits of it an attempt should, perhaps, be made to do away with the gastric retention by pyloroplasty, gastro-enterostomy, or pylorectomy. A pylorectomy was performed in Gumprecht's case some time after the last attack of tetany, but unfortunately the patient after doing well for a few days died from peritonitis.

In conclusion, I will make a few remarks on duodenal carcinoma. Its rarity is obvious from the statistics given by Ewald.[70] Thus, among 1184 cases of intestinal carcinoma, in only 17 cases did the new growth occupy the duodenum. The proportion of duodenal to intestinal carcinoma was thus 1 in from 60 to 70. This accords fairly well with Schlesinger's[71] figures (1 in 60) taken from the post-mortem reports in Vienna. Pic[72] has made a very elaborate study of duodenal carcinomata and he divides them into three groups according to their situation. When placed above the common papilla they are indistinguishable from carcinoma of the pylorus. When situated below the papilla there is a permanent reflux of bile and pancreatic juice, and when round about the papilla they produce mixed symptoms. My case could not be distinguished during life from carcinoma of the pylorus; it has been pointed out that bile may regurgitate through a rigid pylorus. The growth surrounded the duodenum and produced marked stenosis with dilatation of the upper duodenum and stomach. The papilla lay in the middle of the growth but the common bile-duct was not obstructed and there was no jaundice. In Schlesinger's case, in a woman, aged fifty-eight years, the growth was of the size of a gulden piece and extended up as far as the papilla. There was no stenosis of the duodenum and therefore no dilatation of the stomach. There was no vomiting until the last few weeks. Jaundice was present and became intense towards the close. Secondary nodules were present in the liver. In the case reported by Mauclaire and Durrieux[73] the non-ulcerated growth extended for three-quarters of its length round the lumen of the gut and the papilla was placed in the middle of it. There were much pain in the epigastrium and vomiting, but no jaundice. The growth had produced more acute symptoms of obstruction, but as yet no dilatation of the upper duodenum or stomach.

Leeds.

A CASE OF TETANUS TREATED WITH TETANUS SERUM; RECOVERY.

BY DAVID SIME, M.D. GLASG.

ON July 2nd, 1897, a strong, healthy youth, aged seventeen years, had a fall from his bicycle and cut his right hand whilst turning sharply from a country road into a farmyard. The wound, which was on the hypothenar prominence of the hand, was about three-quarters of an inch in extent and it was found to be not merely bleeding but grimed with dirt. In consequence of this latter fact, rather than of the bleeding, the patient, with the companion who was with him, repaired to the village pump and sensibly scrubbed the wound thoroughly "for a good half hour." So little injury otherwise was incurred that he was able to return home on his bicycle, a distance of at least eight miles. Thereafter, apparently, the wound healed satisfactorily and on returning to town, which he did in a few days, he at once resumed his business duties, looking so vigorous and well that his friends congratulated him on the fact. On July 12th, however—i.e., on the eleventh day after the accident, the latter by this time having been practically forgotten—he felt an unaccountable heaviness about the lower jaws and a slight difficulty in mastication and swallowing. These were the first indications of anything like a toxic result of the injury. The incubation period, therefore, of this particular case was not less than 10 days. Next morning the heaviness of the jaw and the difficulty of mastication were slightly increased, but these symptoms were in no way referred to the accident either by the patient or his relatives. Nevertheless, they were so persistent that on the same day he took advice on the matter in the city and having been reassured by the medical man as to their transient character he ignored them as well as he could. This, however, was found to be impossible, so much so that on returning home he called upon me on the way, this being the first time I had seen him. I then found that he could only open his mouth about half its normal extent. There was no other muscular difficulty unless a slight thickness of speech and uneasiness in swallowing. He could rise from his chair, stand, and walk about without difficulty, and the hand grasp was normal and even strong, and equally so on both sides. The wound in the hand was quite healed, with a tolerably dense fibrous cicatrix, and there was still some black "dirt" ingrained in the scar, but pinching of the latter gave no pain and there was no inflammation whatever either here or in any part of the arm. Next day, July 14th—i.e., the third morning after the first symptoms had set in—he still courageously went to his office, but he was unable to stay for more than two hours; a certain stiffness in the loins and back had set in and he found difficulty in sitting on his office stool for more than a few minutes at a time. He was sent home by the heads of the firm. On his way home he again called upon me and I now found that in addition to the difficulty of opening his mouth, which had increased, there was a slight rigidity of the muscles of the back and of the right hand and arm, the hand grip being less pronounced than that of the left side, which was in no way impaired. He rose from a chair with difficulty and his walk was somewhat stiff and unsteady; he was also restless and nervous and had an anxious, scared look, which was altogether foreign to him. On the 15th—i.e., on the fourth day of the disease—he remained at home and, after a hot bath, for the most part in bed; but although not in any way materially worse he was yet in no way really improved, the muscles of the jaw and neck being constantly more or less rigid, with a tremor occasionally running through the rigidity, and the muscles of the right arm and back were still disagreeably stiff. Nevertheless, he could yet masticate, although with increased difficulty, and his appetite was excellent. Early in the morning of the 16th—i.e., on the fifth day of the illness, I was hastily summoned and found him in a deplorable condition. He was lying in bed, rigid, arched, and trembling, with great drops of sweat rolling down his face. It was quite impossible for him to open his mouth and within the last two hours he had for the first time repeatedly bitten through his tongue, which was still bleeding slightly. The expression of combined agony and despair in his face was now pitiful, all the more so that he was bearing his appalling sufferings so stoically. The centre of disturbance seemed located mainly, if not exclusively, in the upper tracts of the spinal substance. Twitching of the facial muscles, with the characteristic facies sardonica, was marked, whilst rigidity of the neck and of the right arm and hand was hardly less pronounced. The muscles of the lower back and loins and of the lower extremities, on the other hand, although occasionally rigid, were at this time not anything like so much so or so excruciatingly painful as those of the upper levels of the body. The slightest irritation in the region of the right shoulder-blade immediately induced a spasm.

It was obvious, then, that complete "intoxication" of the spinal substance with the virus and in its highest and most important tracts had at last taken place. But in this connexion it is not without interest to note that it took actually four days after the disease had set in before this result was fairly accomplished. In other words, manifestly enough, for four days after the incubation was over virus was still being steadily eliminated into the circulation by the micro-organism in the peripheral scar. On the whole this, the fifth day, was, perhaps, the worst and most excruciating of the entire illness. In spite of bromides and morphia and other sedatives, and in very large doses, the spasms continued with decreasing intervals of rest, the chief source of distress being the spasm of the lower jaw and the biting of the tongue which it occasioned. By night he had calmed down somewhat, but he slept not at all, and the paroxysms recurred at

less and less intervals as the night advanced, the spinal site of disturbance being still centred mainly in the upper tracts. It was now necessary for him to be tended night and day without cessation and fortunately his parents proved as intelligent attendants as they were anxious and devoted. On the sixth and seventh days of the illness he was no better, the paroxysms, on the contrary, increasing in frequency and severity; and, both by night and day he but dozed occasionally, invariably awakening with a violent start and a paroxysm of spasm. The latter was still mainly centred in the upper tracts, but was now steadily implicating the loins and lower limbs, the lumbar not less than the bulbar swelling becoming gradually involved. The twitching of the face with the facies sardonica by this time had all but disappeared; but the clenching of the jaws with the crushing of the tongue was more frequent than before. He now only could take liquid nourishment, but of this he took plenty, his appetite remaining excellent; his pulse, too, was strong and regular; the temperature was normal and he passed urine freely and without difficulty. The bowels were cleared out by an injection of soapy water.

On July 19th, the eighth day of the illness, as there was no sign of improvement, but quite the reverse, Dr. Pye-Smith was summoned for consultation. After a careful examination of the patient, he was able to completely eliminate any possibility of a surgical injury to the spine, possibly arising from the bicycle accident, and the diagnosis of tetanus was established. Most formidable as the case was, and in spite of the appalling mortality of tetanus, the prognosis determined on was not altogether without hope, partly on account of the vigorous youth and the continued strength of the patient; partly on account of the soundness of his nervous system as a whole; but mainly on account of the considerable length of the incubation period—ten days—and the already considerable duration of the disease itself—eight days—death not unfrequently occurring on the sixth or even the fifth day. As the patient had slept so little a change was advised in the sedative, and consequently a mixture of tinctura opii and of tinctura cannabis indicæ was prescribed, 15 minims of each drug in every dose, and a dose to be given every four hours, or oftener, according to the severity of the malady. The case, too, was deemed a favourable one for trying the tetanus serum treatment. At bedtime the patient had the first draught of the opium and Indian hemp mixture and thereafter he had four hours' sleep, the longest he had had since the disease was fully established. It must not be forgotten, however, that he was at the time well under the influence of the bromides, &c., for the mixture never again had exactly the same delightful effect. Although he slumbered for four hours the paroxysms never really ceased, the grinding of the teeth, the biting of the tongue, and the arching of the spine, with muffled moans, recurring with the same mournful periodicity. On the morning of July 20th—i.e., the ninth day of the illness—the serum arrived, and at about 9 A.M. (after clearing out the bowels with an injection and giving an extra large dose of the opium and Indian hemp mixture) I inoculated in the right hypogastric region—the Pasteurian site for hydrophobia—10 c.c. of the liquid. Every precaution was taken to ensure that the hypodermic needle was sterilised, the instrument (which was a new one) being taken to pieces, and the pieces boiled together for five minutes, and the skin of the abdominal wall being well sponged with a disinfectant lotion. No uneasiness whatever was caused by the inoculation, and the slight subcutaneous swelling which was occasioned by it in the course of the day gradually disappeared. The paroxysms of spasm, however, were in no way reduced either in severity or in frequency, and the centre of disturbance was in addition becoming stronger every hour in the lower levels of the spine, the entire spinal substance being now apparently involved. So severe and widespread and so frequent were the spasms that the Indian hemp and opium mixture was administered every two hours. Nevertheless towards evening I noticed that, although the spasm of the loins and abdominal walls and of the lower limbs was increasing, the facies sardonica was obliterated. The spasms of the jaw were less pronounced and the patient could open his mouth somewhat better than he had done for some days. Impressed with this fact I determined to give him another subcutaneous injection of the tetanus serum; and this I did about 10 P.M., using the same precautions as before, in the left hypogastric region. On this occasion, in spite of an increased dose of the Indian hemp and opium mixture, he by no means slept so well, but although the paroxysms continued unabated, steadily becoming more pronounced in the loins and lower extremities, he slumbered uneasily for two hours. The limbs and lower spine were supported by pillows, which gave him some comfort. Although not any better, but emphatically worse in the lower levels of the body, before leaving I noticed that the spasm of the jaws was distinctly less frequent and, moreover, that he did not bite his tongue so frequently. Next morning (the tenth day of the illness) I learnt that he had passed a very bad night but that he had not bitten his tongue for four hours. The spasms were apparently becoming stronger in the lower and slightly weaker in the higher levels of the body, and his spine was in a condition of more or less constant arch. The spasms in the loins and lower limbs became in the course of the morning so excruciating that Dr. Pye-Smith was again summoned. By the time he arrived there was no indication of the subcutaneous injections in the hypogastric sites, but a slight erythematous eruption had developed itself over the thighs and abdominal walls. This was at least proof that the serum was having some constitutional effect, which was still further evidenced by the fact that by 10 P.M. the temperature, which hitherto had been practically normal, rose to 101° F. A continuation of the opium and Indian hemp sedative was advised, as, if it did not reduce the severity or frequency of the spasms, it unquestionably induced a certain amount of sleep; if it did not soothe the spinal irritation it at least calmed the brain well. Another subcutaneous injection of the tetanus serum was also recommended, providing the spasms did not soon materially abate. As, however, the erythematous eruption had very considerably increased over the body by the next day, the 22nd, or the eleventh day of the illness, the parents demurred about the further use of the serum unless it should prove absolutely essential. By this time the biting of the tongue had completely ceased and the maximum of spinal disturbance was steadily shifting down the cord, by much the worst of the spasms being now in the small of the back and in the thighs. If the biting of the tongue or the spasmodic distress of the jaws and neck should at all recur, much less increase, if, in other words, there should at any time be any indication whatever, however slight, of a fresh "intoxication" of the upper levels of the spinal substance or of any level higher than the lumbar swelling, it was my intention to repeat without delay the inoculation of tetanus serum, and this the parents very sensibly agreed to and fully empowered me to do. After the tenth day of the illness, however, any indication of a fresh implication of the superior tracts of the cord, with biting of the tongue, &c., never again recurred, so the necessity for repeating the serum inoculation did not arise. That it was still acting constitutionally was obvious, for the erythematous eruption spread over the entire body in a bright lobster-red scarlatinoid rash, the temperature rising to a little over 102°, but this temperature was not maintained for more than two nights, and in the course of a week the eruption disappeared in scales and the temperature became strictly normal. All this time, however, the severity of the spasms in the back and legs continued unabated, and if there was no indication of any increase or spreading of the affection upwards to its original site, there was no proof whatever of the character or severity of the spasms, such as they were, being diminished. Furthermore, the Indian hemp and opium sedative had by this time to be materially increased in order to induce any sleep at all, and even when induced the paroxysms of spasm seemed but slightly influenced thereby. These facts, taken in connexion with the ominous contraction of the pupils, which was now revealing itself, induced me to try chloral hydrate. On the 24th, or the thirteenth day of the illness, I accordingly gave, at 10.30 P.M., a draught composed of 20 grains of chloral hydrate and 30 grains of bromide of potassium and waited for a couple of hours to watch the result. Very little effect was produced; I therefore repeated the dose, and the spasms soon became distinctly less severe and the patient fell into a long but troubled sleep. All night long he was delirious and at 3 A.M. I was summoned. The delirium, however, was clearly due to the chloral hydrate, and to this alone, for hitherto, and in the worst of his agonies, the patient's mind had been marvellously undisturbed. By this time I noticed that the spasms, even of the loins, were distinctly less pronounced, and that in his restless sleep he moved about with more freedom than he had yet done

since the fifth day of his illness, or when the complete intoxication of the spinal substance had occurred. Next day, the fourteenth of the illness, he seemed decidedly better, the paroxysms of spasm being much less pronounced, and, on the whole, he passed a fairly quiet day, much calmer than he had yet enjoyed. At night the Indian hemp sedative with 20 grains of chloral hydrate were administered and he passed one of the best nights he had yet had. I wrote to Dr. Pye-Smith at this stage as to the best sedative now to administer and he strongly recommended the continuation of the chloral hydrate, with, in addition, a glass of stout every night. From this time the progress towards recovery was rapid and extremely satisfactory, the paroxysms became distinctly less severe and less enduring; for the most part they were mainly confined to the legs and occurred chiefly in the evening before his night draught and when he was most exhausted. His appetite increased, he was now taking regularly a mixture of peruvian bark and dilute phosphoric acid and he could masticate food fairly well. On the 29th, the eighteenth day of the illness, the bowels for the first time moved spontaneously. On July 31st and August 1st, the twentieth and twenty-first days of the illness, he had the very last flickering indications of anything like spasm. He now only had the sedative mixture at bed-time and when he could not otherwise go to sleep, and he slept for hours without the slightest sign of spasm. On August 2nd he twice got up for an hour and his movements were good and, although very weak, perfectly normal. He now could bring his arms around his head and both sit with ease on a chair and rise from it with the same freedom. By the 7th he was so decidedly improved that his father and mother were able to take him to the seaside. On the 10th I received a letter from his father in which he said that his son "stood the journey well and is already showing great benefit from the change; he is gaining strength daily."

What influence had the tetanus serum on this case? It can hardly, I think, he said that it was "antitoxic," or, in other words, that it destroyed or aborted the "virus" which had been eliminated into the circulation, for the frequency and the severity of the paroxysms of spasm were in no way reduced by it. The amount of virus which had been thrown into the spinal system by the fifth day of the illness remained for at least a week after the subcutaneous inoculations of serum and in spite of these apparently the same. The amount, however, did not increase. Now, before the fifth and sixth days, it is certain that there was a continuous elimination of virus into the spinal substance, with fresh points of intoxication every few hours. Did this process cease on the sixth day? If it did not cease is it possible that the serum, although in no way antitoxic or antidotal, nevertheless prevented any further elimination of the virus by acting on the specific micro-organism which elaborated it and therefore prevented any fresh intoxication of the higher levels of the cord? If this were so it was a very great result and rendered ultimate recovery but a question of time and strength. With another such case I should employ the treatment at the earliest possible opportunity, for if the serum be in reality a germicidal agent even more than an "antitoxin"—which from this case alone there is reason to show—the sooner it is used the better. There is no reason why it might not be used for every suspicious wound and not merely as a preventative inoculation, but even as a lotion itself. One fact is certain from the case before us—that it does no harm, however much good. Again, it is of interest to note that the wound in this case was received in the country and at a farmyard. How often does this occur? Tetanus is a disease of the country much more than of the town, there being good reason to show that an old garden, a badly-drained stable, or a badly-drained farmyard is the peculiar haunt or "home" of the tetanus bacillus. If this be so a wound such as that incurred in this case must be of pre-eminent danger and should receive the promptest and the most effective of preventive treatment.

Harringay, N.

FATAL POISONING BY MUSHROOMS.—An inquest has been held at Llandaff, Glamorganshire, on a man, aged forty-four years, who died after eating mushrooms which he had gathered. The widow stated that she and the children had taken them without any ill-effects. After hearing the medical evidence the jury returned a verdict of "Death from poisoning through eating mushrooms."

CASE OF TETANY WITH DILATATION OF THE STOMACH; DEATH.

BY JOHN SOUTTAR McKENDRICK, M.B., C.M. GLASG.,
LATE RESIDENT PHYSICIAN TO THE GLASGOW WESTERN INFIRMARY.

WHILE acting as resident physician in the wards of Sir William Gairdner I had an opportunity of observing that somewhat unusual nervous disorder, tetany in the adult. As I have noticed that a few cases have already been recorded of tetany resulting from gastric dilatation I take the liberty of publishing this case, which, if nothing more, may interest those who are collecting statistics on this subject. Almost 50 years ago Steinheim in Germany and Dance in France described this disease, but it was not until Trousseau in his masterly way wrote on the subject that the disease became much known. Trousseau called it "tetanilla"; for the name "tetany" we are indebted to Corvisart, who described the condition in 1852. Cases have been reported by Moxon, Wilks, and Abercrombie, and by Riegel, Erb, Weiss, and others, and the disease has been fully discussed in lectures by them. The description of the complaint is fully given in Gowers's and Ross's text-books on diseases of the nervous system. Moxon described the close similarity between tetany and certain symptoms developed from poisoning by ergot, although he noted that in the latter the symptoms passed on to tetanus. Foord has also mentioned a case of hysterical spasm which closely simulated this disease, while Cheadle[1] instances cases where patients who in childhood had convulsions in adult life suffered from tetany. He also notices the similarity of the disease in adult life and in childhood. Tetany is considered by some to be of a rheumatic nature as it so frequently occurs from exposure to cold, while the joints are painful and often swollen from œdema. Trousseau has described it as the "rheumatic contracture occurring in nurses," and a case is reported by Cheadle of a girl, aged seventeen years, who had tetany, and who, when she was twelve years of age, was the victim of chorea, a disease closely related to rheumatism. Amongst numerous other causes assigned to this obscure complaint may be mentioned anæmia, intestinal disorders, and dilatation of the stomach, while it has also been observed during lactation and in pregnancy. The etiology of tetany is fully discussed by Stewart of Canada,[2] who classifies various types of the disorder as follows: (*a*) when it is epidemic and acute; (*b*) when it is chronic from debilitating diseases; and (*c*) when it is the result of thyroidectomy. He points out that recovery is frequent and that the malady has a low death-rate. He notes, however, that out of 78 thyroidectomies 13 had tetany, of whom 6 died; and he also mentions the fatal tendency in cases where dilatation of the stomach is a complication or possibly a factor in the causation of the disease. Cases of tetany with gastric dilatation have been described by Kussmaul, Gerhardt, Dujardin-Beaumetz, and Müller, the latter noting the mortality in the few cases he had met with as 66 per cent. It will be my object to describe this case as fully as possible and afterwards to discuss it shortly.

A man, aged twenty-six years, was admitted into the Western Infirmary on June 14th, 1897, complaining of cramps of the hands and arms of four days' duration. It appears that the patient was at work as usual on June 10th, apparently in his ordinary health, when he was suddenly seized with a tingling sensation in his hands and then in his legs, which afterwards extended up to the elbows and knees. He had the same feeling also in his face. He commenced to feel drowsy and his eyes felt heavy. He soon noticed that his hands and feet were somewhat stiff and shortly afterwards he had severe cramps in the same parts with acute pain. With some difficulty he was able to walk home, as he says that the legs did not share long in the extreme spasm but became only stiffened. His head was painful and he felt as if it and his tongue were swollen, and he had difficulty in articulation. Drowsiness supervened and he soon became very sick, vomiting a small quantity of bright red blood. The spasms in the hands, the arms, and the face occurred every six or seven minutes, giving him great pain, but during the interval the arms and

Digitized by Google

hands remained in a contracted position and felt numb, cold, and dead. He said that he was not exposed to cold before the onset of his illness. He passed his urine naturally but it had been small in quantity and not voided at too frequent intervals. His bowels had always been constipated. Apart from "a fever" which he had when a child, the name of which he had forgotten, he declared that indigestion had been his only ailment. For twelve years he had been troubled constantly with headache, pain in the stomach, aggravated by food, and, as a rule, relieved by vomiting, and this vomiting had been more severe during the last few months. The vomited matter was sour to the taste and was of a greenish-yellow colour. He had never had rheumatism, swelling of the face and legs, or venereal disease. He had never had cramps before nor had he had convulsions as a child. There was nothing unusual in the family history except that his father was subject to indigestion and vomiting in the same way as himself. His father had never had cramps in the extremities to his knowledge.

On admission to the infirmary the patient was put to bed. He had a drowsy, unintelligent appearance; his eyes were partly closed and it was only with an effort that he could completely open them for a short time. He was slow in answering questions and his articulation was thick. The lips, the nails, and the backs of the hands and the forearms were livid. The arms and hands were cold. There was no œdema of the ankles or of any other part of the body, nor was there any clubbing of the finger tips or marked curving of the finger nails. The temperature was 98·6° F. and the respirations were 20. The pulse was of moderate tension, numbering 96 in the minute. The tongue was protruded in the middle line and was slightly tremulous; it was dry and fissured and was covered with creamy fur, and the papillæ were enlarged. The pupils were equal and small, but responded to light and in accommodation. The hands were equally bent at the wrists and were inclined to the ulnar side. The fingers were flexed at the metacarpo-phalangeal joints, although the terminal phalanges were in extension. The thenar and hypothenar eminences were contracted, leaving a cup-shaped depression in the palm, and the muscles of these eminences were in a state of tremor. The thumb was forcibly adducted into the palm and was partly covered by the fingers. (This position of the hand has been described by Trousseau as like the "accoucheur's hand.") The arms were bent at the elbows, but they could be straightened and the hands and fingers bent into their normal positions without causing pain. There was no contracture of the legs. The spasms occurred every few hours. During the spasm the arms were more bent at the elbows, the thumb was more forcibly pressed into the palm, and was more closely surrounded by the fingers. The forehead was drawn upwards and the sides of the mouth backwards, which gave the face a grinning expression. The abdominal wall was tense and hard. In the intervals between the spasms the muscles of the arms, the hands, and the fingers were in a state of semi-contracture although he had no pain. Greater pain was felt during the spasm in the left hand than in the right, and it was noticeable that the shape of the left hand was more altered than the right. There was nothing abnormal detected in the lungs on percussion or auscultation, although when he was asked to take a deep inspiration he performed a series of irregular jerking movements. The heart was perfectly normal. As regards the abdomen, the liver was of normal dulness; there was great resistance of the abdominal wall and no evidence on examination of a dilated stomach. The specific gravity of the urine was 1017, it gave an acid reaction, was of a pale amber colour, and there was distinct albumin but no sugar, bile, or blood. Tube casts were never found. The patient died on June 19th. The tetanic contracture of the muscles of the arms and hands were present to the last although the severe spasms only occurred at occasional intervals. Vomiting was a constant symptom and the vomited matter was usually of a dark-brown colour which gave no blood or biliary reaction and certainly was not in harmony with the idea of a dilated stomach. The urine which was collected always contained albumin, but otherwise it was not remarkable. During the last thirty hours before death only a few ounces were passed and at no time did there seem to be much urine in the bladder. On the day before his death the patient had a sudden attack of dyspnœa. He then became cyanosed and his respiratory efforts were irregular and jerky, with considerable periods of apnœa. His pulse became quicker and he was totally unconscious. He had another similar attack on the day of his death. The treatment consisted of chloral and bromide of potassium in frequent doses; calomel and croton oil were given for the constipation. The patient was fed latterly by the rectum and stimulants were freely administered. A post-mortem examination was obtained, but unfortunately permission to examine the head was refused. There were found marked gastric dilatation, cicatricial contraction of the pyloric end of the stomach, and marked enlargement and caseation of the glands around, with intimate adhesion to the wall of the stomach and the cicatrised area. For this description of the appearances presented at the necropsy I am indebted to Dr. Lewis Sutherland.

I now venture to make a few remarks on the causation, symptoms, neuropathic heredity, diagnosis, and pathology of the disease, with special reference to the case as above described.

Causation.—Kussmaul and Nönsten have noted transient albuminuria in two cases. This patient had albuminuria. Is the tetany, then, one of the sequelæ of Bright's disease, or is it the result of gastric dilatation? The former supposition is, I think, negatived by the facts that no blood or tube casts were found in the urine, that the patient never had œdema of the ankles, the face, or other part of the body, and that he never at any time had polyuria or deficiency of sight. The periods of apnœa which occurred towards the end of his life were not due to Cheyne-Stokes breathing, but rather to a spasmodic condition of the diaphragm and muscles of the chest interfering with the physiological processes of respiration.

Symptoms.—Before the onset of cramps the patient had certain nervous premonitory symptoms[3] such as tingling sensations in the extremities, a feeling of coldness of the limbs, drowsiness, heaviness of the eyes, and swelling of the head and tongue. There was no pain on extension of the fingers, hands, and arms as would have been expected. The contracture was not quite equal on the two arms, being greater on the left. The spasms commenced in the arms and hands and afterwards affected the legs and feet. A permanent stiffness of the legs and feet resulted after the first few spasms had occurred, while the severity of the spasm increased in the arms and hands and affected the muscles of the face and abdomen as well. Ross says that the muscles of the facial expression and tongue are rarely involved, and Gowers mentions that when the muscles of the face are involved it is usually a severe case. Although the spasms in this case were intermittent, especially at the commencement, yet towards the end there was a more continuous spasm, interrupted only at occasional intervals by contractions of a severer kind. Ross mentions that the mental faculties are always unimpaired. In this case they were undoubtedly dulled and the memory had likewise suffered.

Neuropathic heredity.—Abercrombie has noted cases where a distinct neuropathic heredity could be traced and also where several members of the same family had the affection. In the present case no such history could be discovered, although it is a curious and interesting fact that the patient's father has had symptoms referable to the stomach of a nature precisely similar to his own.

Diagnosis.—The order of the symptoms as they occurred in this case was closely analogous to that described by Trousseau in his article on Tetany. No other affection has a series of symptoms precisely similar. Hysterical contracture very commonly affects only one side of the body or individual members, while in tetanus prolonged contraction of the masseter muscle is an early and characteristic symptom. The "Trousseau phenomena," so graphically described and of such diagnostic importance, were not tried in this case. They consist: (1) in the production of spasm in the hands and arms by pressure on the nerves or vessels of the forearm; (2) in the increased irritability and excitability of muscles and nerves to both faradaic and galvanic currents (it has been observed also that only in cases of tetany do we get anodal opening tetanus); and (3) in the disappearance of the spasm when the affected part was immersed in cold water.

Pathology.—Numerous are the changes in the brain and cord which have been described by writers as probably the pathological lesion in cases of tetany, and still more

[3] Gowers: Diseases of the Nervous System, vol. i., p. 648; and Ross; ibid., vol. i., p. 524.

Digitized by Google

numerous are the speculative theories which have been offered as to their causation. Thickening of membranes, small inflammatory areas in the brain cortex with exudation of leucocytes, hæmorrhages, and disorganisation of brain cells have been described and their significance discussed in cases of tetany, but are not similar changes frequently met with in many other diseases? The microscopical pathology of brain structure is yet imperfect and furnishes us with few positive data which can guide us in clinical observation. But is this lesion an affection of the centres—the brain or the cord—or is it due to pathological changes in the nerves? Russel[4] supposes it to be due to the unopposed operation of the cerebellar influence—a view supported also by Hughlings Jackson.[5] Gowers[6] thinks that the pathology of the disease is vague, but he believes that there is some affection of the nerves and cerebro-spinal centres, and this view is supported by many authorities. The suggestion that nerves themselves may be the seat of the disease is negatived by the fact that "muscular spasm is rarely caused directly by chronic disease of peripheral motor nerves."[7] The suggestion offered by Cheadle[8] appears to me to be a fairly reasonable one, and one which well accounts for the tetanoid contracture in the present case. It is that the body becomes debilitated from a gastric or intestinal trouble with the result that there is a general weakening of the nervous system, with a consequent over-excitability of the motor cells of the cord. This condition of over-excitability is the predisposing cause, but there is also an exciting cause, such as diarrhœa, teething, &c., which acts reflexly on the cells of the cord, causing a series of impulses to pass along the neur-axons into the nerves supplying the muscles and producing a tetanoid contracture. In the present case no doubt the patient's strength had been gradually undermined by deficient nourishment owing to gastric dilatation. We may then suppose the cells of the cord had become impoverished and over-excitable and that a temporary acute gastritis or the absorption into the blood of ptomaine substances produced by fermentative changes in the stomach had acted as exciting causes and produced tetany. It is not easy to show a causal relation between dilatation of the stomach and tetany due to heightened reflex excitability of the cord except on the supposition that in certain cases specific substances of the nature of ptomaines may be generated in the stomach by fermentative processes, and that these substances raise the excitability of the cells in the cord. It is only in rare cases of dilatation of the stomach that this condition is accompanied by tetany; but, on the other hand, while fermentative changes due to micro-organisms are always present in cases of dilated stomach, it does not follow that the products of fermentation are always the same. It seems more reasonable to conclude that the reflex excitability of the cord is heightened by the action of specific substances than that this is due merely to deficient nutrition, as has been suggested. Clinically, therefore, it is important to take the warning that a dilated stomach in which fermentative processes are going on may be the precursor of a serious disorder of the central nervous system. It must be admitted, however, that there is no proof that a state of debility from exhaustive disease causes hyper-excitability of the motor cells of the cord and consequent tetany. The condition is by no means so common as we might expect if this were the sole cause of the disease, and a consideration of this case and of the literature of the subject obliges me to conclude that its real origin is still obscure.

It was unfortunate that no examination of the head could be obtained after death; still, it is important to observe that had we not had the post-mortem examination I am afraid the presence of an excessively dilated stomach might have been overlooked, which would have left us in a greater uncertainty as to the source of the tetany and the fatal issue of this case.

SOME NOTES ON MALARIA AS SEEN IN RHODESIA.

BY ARTHUR DUNLEY-OWEN, B.Sc., M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE BRITISH SOUTH AFRICA COMPANY; MEDICAL OFFICER TO THE TERRITORIAL FORCES.

IN every form of disease it is an acknowledged fact that the vitality of the body must be lowered before the specific germs of any disease can begin to manifest themselves in the system, for it is self-evident that wherever we may be we are all of us breathing air laden with germs and that it is only the inherent vitality of our tissues which prevents us from falling victims to every disease we may come in contact with.

Malarial fever is to be found universally distributed all over the world, though in greatly modified forms where civilisation and consequent drainage of ground, good food, and comfortable dwellings are obtainable. In Europe, for instance, it is scarcely ever met with and most probably only in those who have previously lived in some parts of the tropics. In Rhodesia, as in most new countries, malaria is very prevalent owing to a variety of causes or conditions, a few of which I will enumerate. Those arising from the land itself, or "endemic causes," are: low-lying country, porous soil, alternate spells of heavy rainfalls and intense dry heat causing rapid growth of rank vegetation, which is quickly dried up and withered by the sun, and the heavy rains following convert the whole into a mass of decaying matter, most pernicious to those living near; also the overturning of fresh virgin soil, necessary in farming, appears to produce a severe form of malarial fever. The malarial poison also seems to be most virulent an hour before and an hour after sunrise and I have made cultivations of the malarial bacillus obtained at this time of the day from the grass and soil, but only to the height of 4 ft. from the level of the soil—a curious fact, and one with regard to which I should like to know whether it has been substantiated by the observations of others.

Another note of mine may prove of interest also: it is with regard to "horse-sickness," an almost always fatal disease, which I consider to be malarial fever in the horse, inasmuch as I have made cultivations from and obtained the malarial bacillus in the blood of an affected animal. Now it has been proved that horses will not develop this sickness if they are stabled an hour before sunrise and not let out again until about 9 or 10 A.M., when the grass is dry. Numerous cases I have noted have shown the following facts to be indisputable: (1) horses turned out to grass during the day and stabled at night seldom or never take "horse-sickness"; (2) horses left out all night but stabled before sunrise and not turned out to grass until 10 A.M. continue healthy; (3) horses kept in at night and turned out just before sunrise always get "horse-sickness" sooner or later; and (4) this "horse-sickness" is not contagious inasmuch as others in the same stable do not contract the disease.

The conditions which I consider facilitate a tendency to malarial fever, and which may be classed as "ethnological causes" are: excessive spirit-drinking (there is a recognised form of malarial fever termed "whisky fever"), poor quality of food (fresh meat and vegetables being quite unprocurable in parts), tinned meats, jams, vegetables—in fact, everything is tinned, and becomes in time quite nauseous.

Then, again, I find fever far more frequent amongst men than among women and more single men are victims than married ones. This I put down to the fact that women are not exposed to "roughing it" like men and that married men have home comforts which are impossible for the single. The following is a typical single life: there are "messes" at the different hotels, and most single men prefer joining one of these to feeding themselves in a solitary room about 12 ft. square by the light of a single candle (candles, remember, are valuable, being from 6*d.* to 1*s.* 6*d.* each); then, after dinner, he goes into the drinking bar—far more inviting than his own quarters—and is therefore bound to drink, and thus gradually acquires habits which sooner or later will land him in a severe attack of "whisky fever."

On microscopical examination of the blood of a patient suffering from an attack of malaria the observer finds numbers of red corpuscles shrivelled up and blackened and

Digitized by Google

others containing bacilli of a crescentic form. The white corpuscles are greatly increased in number and there are also seen numerous giant white corpuscles with patches of black colouring matter in them. The pathology of this I take to be: (1) the crescentic bacilli of malaria invade the red corpuscles and proceed to absorb the hæmoglobin, converting it into melanin, and they also multiply in number (these facts I have demonstrated by examining the blood of a patient subject to malarial fever, but about three hours before an attack of rigors was expected); and (2) after a variable time the red corpuscles burst, setting free crowds of bacilli (this process I have found in blood taken at the period of rigors); the giant white corpuscles absorb the bacilli and apparently digest them, leaving only the melanin which remains as black patches in the corpuscles (this process may be traced by examining the blood of a patient at intervals during a typical attack of fever). The effect of the malarial poison shows itself differently in different individuals, the most usual form being that of high fever, the period of incubation being in most cases fourteen days, during which time the patient has a great feeling of *bien aise*. Towards the end of the incubation he becomes irritable and chilly, generally suffering from nausea, sometimes actual vomiting. At this period he begins to have a succession of rigors, which, however, gradually cease and he becomes feverish, with a full, bounding pulse. Without drugs this stage lasts from six to eight hours, when he begins to perspire, the temperature falls, and he sleeps for several hours, awakening without fever. After a length of time, varying from twenty-four hours to a week, if the person has not been placed under the influence of drugs the fever occurs again in exact similitude to the initial attack and this may recur at intervals for months. There is also a variety of malarial poisoning without much elevation of temperature, but with marked cerebral symptoms resembling meningitis. It is a most fatal variety and post mortem no signs of inflammation of the meninges can be seen.

Residents in Rhodesia are also, I find, liable to attacks of dysenteric diarrhœa which will not yield to opium or ipecacuanha, but rapidly gives way to tincture of perchloride of iron with quinine and arsenic. I have also seen what were apparently syphilitic ulcers, especially on the legs and thighs, which proved most obstinate to the usual specific treatment, but got well at once with the iron, arsenic, and quinine mixture, with a dusting powder of quinine locally. On healing these ulcers leave a permanent brown stain on the skin. I consider both diarrhœa and ulcers due to malarial poison and the brown discolouration of the skin is possibly the local deposit of melanin from the bacilli.

The sequelæ of malarial fever are only what may be naturally expected, the first and most important being the intense anæmia which is so often found and which requires lengthy treatment by iron and arsenic with, if possible, change of air. This anæmia causes anasarca of the most dependent parts—viz., legs and feet—but this cures itself as the anæmia decreases, as also does the intense weakness, amounting in some cases to temporary paralysis; whilst another result of the poverty of red-blood corpuscles is shown in the dizziness, partial blindness, and flashes of light experienced by some on recovering from a severe attack.

With regard to treatment every treatise on medicine and also the so-called popular handbooks describe quinine as a "sheet anchor" in malarial fever, but my experience tells me there is no greater mistake. The result is that nearly everyone coming to Africa brings enormous quantities of quinine tabloids, which they take *ad lib.*, and also dose their friends, independently of any advice from a medical man, and they fully believe they are rendering themselves proof against fever. These large doses of quinine—and it is not uncommon to find persons taking from two to three drachms a day—produce an utter rottenness of the constitution. There is a distinct quinine cachexia, easily recognised by those who see it often, and when one of these individuals falls a victim to an attack of fever he generally has it badly. I have found the most successful treatment to be absolute rest in bed, a 15 gr. dose of antipyrin to begin with, followed in an hour by the following mixture: 10 minims of tincture of perchloride of iron, 5 minims of hydrochloric solution of arsenic, with water to 1 oz. 1 oz. to be taken every four hours with a 5 gr. tabloid of sulphate of quinine. At bedtime I generally give about 5 gr. of calomel, followed in the morning by a dose of some effervescent saline. In most ordinary cases of fever this treatment cuts short an attack under twenty-four hours and then I follow up with a tonic course of Easton's syrup in 1 dr. doses with 1 oz. of water three times a day at meals for a month, and I find that most individuals will thus enjoy an immunity from malarial fever for some months at least, although living in an unhealthy district.

With regard to food stimulants are required, especially champagne. This will often stop the obstinate vomiting when even a mustard poultice at the pit of the stomach fails. During an attack I order milk and hot water in equal parts, and in some cases milk with a tablespoonful of brandy to each pint. When the temperature is normal and the paroxysm is over I give any food the patient fancies, and I find this answers well. I have one patient who after an attack of fever eats ravenously of cheese, enjoys it, and, what is more to the point, digests it.

In the "cerebral apyrexial form" as I term that variety with low temperature and head symptoms, which is very fatal, I find, so far, that the best treatment is calomel and sulphate of magnesia in full doses, producing free purgation, giving at the same time the quinine, iron and arsenic as in an ordinary attack. It is happily a rare form. I have only seen 6 cases, of which 1 was fatal; the rest recovered, 3 completely and 2 with some mental aberration, which I am in hopes will prove only temporary.

In Africa "ice-bags" are an impossibility, and yet how often one longs for them. Here, where medical men are rare, being often from 85 to 100 miles apart, it stands to reason that there are many farmers and traders who when they get fever cannot obtain medical advice. For these Messrs. Burroughs, Wellcome, and Co. have prepared cases for me containing five bottles and a thermometer. These contain 25 (5 gr.) tabloids of antipyrin; 100 (5 gr.) tabloids of sulphate of quinine; 100 "Iron and Arsenic Co." tabloids; and 200 (1 dr.) tabloids of Easton's syrup. I order possessors of these when "shakes" begin to go to bed and take three 5 gr. tabloids of antipyrin and one hour afterwards to take one each of quinine and iron and arsenic tabloids, repeated every three hours until the temperature is normal; then to begin with the Easton syrup tabloids, taking one three times a day for a month, and in every case I have been told that these drugs and directions have proved a boon; and whereas the traders, &c., at outlying stations have previously suffered all the wet season from malarial ague, now the initial attack is all they experience for the season.

To sum up, it must be remembered in every case that the malarial parasite destroys the red blood corpuscles, and one method of treatment is to replace them and so raise the vitality of the tissues that they may resist further invasions of the poison.

Enkeldoorn, Rhodesia.

DISSECTING ANEURYSM.[1]

BY JAMES B. COLEMAN, M.D. R.U.I., M.R.C.P. IREL.,
PHYSICIAN TO THE RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, DUBLIN.

THE term "dissecting aneurysm" is applied to cases in which a partial rupture of the inner tunics of an artery allows the blood to become diffused between the coats of the vessel. Having regard to the difference of opinion which exists as to the author of the original description of this very remarkable affection the following extract from Peacock's[2] "Report on Cases of Dissecting Aneurysm" may be of interest: "It has generally been supposed that Laennec was the first writer who applied the term 'dissecting' to this form of aneurysm, but it has been recently shown by Broca that Maunoir employed the same designation and clearly described the formation of aneurysms of this kind in his work published in 1802. A characteristic case is also related by Allan Burns in his work on 'Diseases of the Heart and Aneurysm,' published in 1809." Shekelton[3] published two cases of dissecting aneurysm in 1822, and the preparations are to be seen in the museum of the Royal College of Surgeons in Ireland. Erichsen, in the eighth

edition of his "Science and Art of Surgery," incorrectly refers to this variety of aneurysm "as originally described by Shekelton," and the use of the name "Shekelton's aneurysm" as a synonym for "dissecting aneurysm" is to be deprecated. Peacock, in the paper to which I have already referred, collected 80 instances in which the affection appeared in well-marked form, including 5 Dublin cases published by Shekelton,[4] R. W. Smith,[5] Kirkpatrick,[6] Lees,[7] and MacDonnell respectively. An interesting specimen was exhibited by Connolly Norman at a meeting of the Pathological Section of the Royal Academy of Medicine in Ireland a few months ago. In the earlier published cases of dissecting aneurysm it was supposed that the separation of the tunics of the artery took place between the middle and external tunic; but modern pathologists agree that the blood almost invariably makes its way between the laminæ of the middle coat, so that the outer wall of the aneurysm is formed of the outer strata of the media together with the adventitia. In the vast majority of cases the rupture of the inner tunics is due to their excessive lacerability, the result of atheromatous degeneration. Indeed, out of 60 of Peacock's cases the artery was found healthy in only two instances. Ziegler[8] suggests that in the rare absence of morbid changes in the coats of the vessels, traumatic injury to, or defective development of, the vessel wall is the primary cause of the lesion, and Walshe[9] mentions 2 cases in which dissection of the aortic coats on a limited scale had been abruptly effected as the result of a railway concussion. On the other hand, Rokitansky[10] supposes that in some cases a morbid condition of the external coat deprives the inner coat of support and so predisposes to their rupture.

Dissecting aneurysm is practically confined to the aorta and its large branches, although Ziegler[11] states—on what authority I do not know—that the small arteries of the brain are a usual seat of the affection. The internal rupture is usually situated at the origin of the aorta or in the ascending aorta (it was so in 55 out of 73 of Peacock's cases) but it has been found as low as the end of the abdominal aorta, as happened in Shekelton's cases. The direction of the rupture is generally transverse when it is near the aortic valves, whilst it is more frequently vertical at the beginning of the descending aorta. Ordinarily from one-half to two-thirds of the vessel is torn asunder, although the whole circumference of the artery is occasionally separated. The longitudinal extent of the separation of the tunics varies considerably. As a rule the aneurysm does not extend beyond the ascending aorta, though it is occasionally found to extend into the iliac arteries. In my case the separation of the coats begins at the arch and ends in the left femoral, and in a very remarkable case recorded by Tessier[12] the separation extended from the commencement of the ascending aorta to the left popliteal artery. The dissection not unfrequently is carried along the primary branches of the aorta; for instance, in MacDonnell's[13] and Tessier's[14] cases it extended along the innominate and its branches to the internal carotid; in another case[15] it followed the course of the coronary arteries; in Laennec's[16] case it passed along the cœliac artery and in my case along the right renal artery. Some of the intercostal and lumbar arteries are frequently found to be cut across by the stream of blood "so that a probe introduced into the aortic orifice of one of those little branches passes directly into the aneurysmal canal and traverses this before entering the artery itself, which thus appears to arise directly from the aneurysm."[17] In cases which have ended fatally within a short time there has been only a single opening leading from the aorta into the arterial coats, death having been usually due to the subsequent giving way of the external wall of the sac. This is the common form, comprising 73 out of Peacock's 80 cases. My case is also an instance of it. On the other hand, when life is prolonged for any considerable time the blood is found to have forced its way from the subadventitious sac back again to the blood-stream at some point further on in the course of the vessel. In such chronic cases the new blood-channel acquires an endothelial lining. Shekelton's[18] and Fagge's[19] cases were examples of this variety. The disease is specially common in persons of advanced age, and though it probably occurs more frequently in men than in women there is not the excessive preponderance in males which is the rule in ordinary aneurysms. Indeed, some writers say that it is more common in women. The case which I now relate and the specimen which I exhibit typically exemplify the symptoms and pathology of the early stage of the fully formed dissecting aneurysm.

A man, aged sixty-five years, a house-painter by occupation, was admitted to the Whitworth Hospital under my care on Jan. 13th, 1898, complaining of severe pain in his back and of loss of power in his legs. On the morning of his admission to hospital he was on a ladder papering a room when he was suddenly seized with a violent pain in the lower part of his back and in his left hip. The pain appeared to begin in the lumbar region and to shoot up into his chest and downwards towards his left thigh; it was so intense that, to use his own expression, he "bellowed with agony." He felt faint but did not lose consciousness, and he was able with difficulty to walk across the room to a chair. Within a quarter of an hour his lower extremities were completely paralysed and his left leg was anæsthetic. He was sent to the hospital in a few hours. Beyond the fact that he was a painter there was nothing noteworthy in his personal history and he came of a healthy family. On admission to the hospital he was seen to be a well-nourished, grey-haired old man, but rather anæmic. He was unable to walk, but he could move his legs slightly. He still suffered from severe pain in his back and everything he ate or drank was vomited. He had no longer anæsthesia in his left leg. His arteries, in which there was visible pulsation, were atheromatous and his pulse was high-tensioned. His heart was hypertrophied; no murmurs were audible, but the aortic second sound was greatly accentuated. No sign of aneurysm could be detected, although the patient was carefully examined for it. There was marked arcus senilis and he had a "lead-line" on his gums. His urine was feebly alkaline; its specific gravity was 1014. It was clear and contained 0·2 per cent. albumin and a few hyaline and granular casts; neither sugar nor blood was present. The quantity of urine passed was about the average amount, and he had perfect control over the sphincters of the bladder and rectum. The pain in his back ceased after 12 hours and next day he felt much better and he was able to move his legs freely. The knee-jerks and plantar reflexes were absent. On the following morning he was able to walk a few steps and he expressed himself as feeling almost well. At this period I showed him to the hospital class and diagnosed the case as plumbism and chronic interstitial nephritis with the usual cardio-vascular changes. I pointed out that the history of the attack clearly indicated some vascular lesion of the spinal cord and that the sudden onset, wide diffusion, and intensity of the pain, together with the transient duration of the paraplegia, appeared to justify the further diagnosis of spinal meningeal hæmorrhage. The patient was apparently well about 4 P.M. when he took a drink of milk. Five minutes afterwards he was found dead in his bed, his death having thus occurred about 52 hours subsequent to the onset of the symptoms.

Necropsy.—The post-mortem examination, which was made within 24 hours of death, showed the right pleural cavity to be filled with blood. The pericardium contained a little clear serous fluid. The heart was rather large, there being hypertrophy of the left ventricle. The arch and upper part of the descending aorta were distended, forming a tumour-like mass from which the blood had escaped by a small rent into the right pleura. On opening the aorta its inner aspect was covered with atheromatous plaques and calcareous plates and a dissecting aneurysm extended from the arch at the level of the innominate artery and terminated in the left femoral artery about an inch below Poupart's ligament. A large mass of freshly coagulated blood was effused between the tissues at the level of the arch and the upper portion of the descending thoracic artery, and here the separation of the tunics took place around nearly the whole circumference of the vessel

wall. From the abdominal aorta through the left common iliac, external iliac, and femoral artery the coats of the vessels were separated by a thin layer of coagulum, but no palpable thickening of the arteries was so produced. In the lower part of the aneurysm the dissection of the arterial coats did not extend much more than half-way around the circumference of the vessels.

The microscopic sections which I exhibit are from the left common iliac artery and they show that the blood is effused in the substance of the middle tissue of the artery, so that the external wall of the aneurysmal canal is composed of the outer strata of the media together with the adventitia. The dissection was carried along the coats of the right renal artery, which was also occluded by a thrombus. The lumbar arteries were cut across and their orifices likewise contained thrombi. A large coagulum was adherent to the posterior wall of the aorta at the level of the renal and lumbar arteries. I have not been able to satisfy myself as to the position of the internal rupture of the aorta. There are many degenerated spots in the inner coat of the vessel through which it might have occurred, or possibly it took place at the origin of one of the primary branches of the aorta. The capsule of the left kidney was adherent, the organ being cirrhotic; the right kidney was in a similar condition and was, in addition, cystic; it was extremely engorged with blood and the microscopic sections (which were prepared by Dr. Dargan in Dr. MacWeeney's laboratory) show that a universal hæmorrhagic infarction was present. There was no hæmorrhage in the spinal cord or its membrances. In the light of the necropsy it is not difficult to account for the symptoms of this case. As predisposing causes of dissecting aneurysm the patient had extensive atheroma of the inner coats of his aorta, which was consequently unduly lacerable, and in addition he had hypertrophy of the left ventricle with high arterial tension. The intense pain at the onset of the symptoms was due to the primary rupture and separation of the coats of the aorta by the blood. The paraplegia was caused by the interference with the arterial supply to the lumbar region of the cord, partly from thrombi in, partly from rupture of, the origin of the lumbar arteries. The sudden death ensued on the rupture of the external wall of the aneurysm and the consequent escape of blood into the right pleural cavity. It is rather remarkable that the urine contained no blood and that the amount passed was not noticeably diminished, for the functions of the right kidney must have been completely arrested.

Other cases of dissecting aneurysm have been recorded in which a remarkable series of symptoms was due to the arrest of vascular supply to the brain, kidneys, or cord. Tessier's[20] patient died with symptoms of apoplexy, and a dissecting aneurysm was found extending from the arch of the aorta along the innominate artery and its branches to the internal carotid. Todd's case[21] was characterised by hemiplegia and suppression of urine, and the post-mortem examination showed softening of the brain due to obstruction in the carotids, and the renal arteries were also obstructed. Sainet[22] records a case in which the patient became rapidly paraplegic. In Dickenson's[23] case a policeman after seven hours on his beat was seized with loss of power over his lower extremities, followed by pain, collapse, and death in twenty-four hours. Swaine's[24] case was diagnosed during life, the patient having been suddenly seized with pain in his chest followed by paraplegia. Where the symptoms are liable to such variation it is evident that the diagnosis of dissecting aneurysm must be always difficult and uncertain. In reference to treatment Walshe[25] remarks: "Were the practitioner fortunate enough to divine the occurrence of acute separation of the coats of the aorta it does not appear that, in the present state of our knowledge, the management of the case would be materially improved by his sagacity. Did he fail to diagnose the occurrence, his aim would be to restore the patient from the first shock of the accident, control excited arterial action, and relieve the symptoms as they arose. And it does not appear that art could do more than this were the anatomical nature of the affection understood from the first."

A CASE OF DOUBLE LOBAR PNEUMONIA COMPLICATING INFLUENZA DURING THE COURSE OF ACUTE MANIA.

BY G. J. CONFORD, B.A., M.B., B.CH. OXON.,
ASSISTANT MEDICAL OFFICER TO THE COPPICE HOSPITAL, NOTTINGHAM.

THE following is a case of some interest, showing as it does the possibility of recovery from double pneumonia complicating influenza under conditions of such special difficulty as to render the prognosis almost certainly fatal.

The patient, a woman, aged thirty-seven years, was admitted into the Coppice Hospital, Nottingham, on March 18th, 1898, suffering from acute mania of three weeks' duration, her leading mental symptoms being extreme restlessness, hallucinations of sight and hearing, and obstinate refusal of food. She professed inability to walk and had to be carried to her room. On examination there were no signs of organic disease except at the apex of the right lung, where there was evidence of consolidation, which from the history was presumably tuberculous in character. The pulse was 84 and the respirations were 22 per minute, while the temperature was normal. The pupils were equal and reacted (though somewhat sluggishly) to light. The muscular power generally was fair, but the knee-jerks were greatly exaggerated. The patient was said to be of a highly excitable disposition and for several years had been subject to attacks of *petit mal*. After admission she was very troublesome in the matter of food, being only induced to take it after much persuasion, while the use of the nasal tube was necessary on one or two occasions. On the 22nd the patient had a slight cough and on the following evening the temperature was found to be 101·4° F., but the rate of respiration was not accelerated; the pulse was 92 per minute and no abnormal signs were found in the lungs apart from the condition at the right apex. On the following morning the temperature had fallen to 99·4° and in the evening it was normal; during the night, however, the breathing became very rapid and the face cyanosed, and the night nurse, becoming alarmed at the patient's condition, sent for the medical officer, when the respiration was found to be 60 per minute, the temperature 103·4°, and the pulse very rapid (160 per minute) and of so feeble a quality that a hypodermic injection of 15 minims of ether with $\frac{1}{60}$ gr. strychnine was given, upon which the patient rallied a little. She was then put on strychnine ($\frac{1}{30}$ gr. hypodermically every six hours) and fed four times daily through the nasal tube as it was impossible to get her to take food otherwise and the bowels were acting so frequently that rectal feeding would have been useless. At 6 P.M. the temperature had risen to 105° and the pulse was 168. Signs of consolidation were now observed over the lower hand's breadth of the right lung behind, the previous examination having given negative results. The patient's condition now appeared to be very grave and death was looked upon as imminent. She was fed, however, and 10 gr. of quinine were given with the food, the temperature dropping in the course of an hour to 103·2°, while the pulse had greatly improved. During the whole of the day the patient had been trying to throw the bedclothes off and had passed urine and fæces under her. On the 25th the temperature at 8 A.M. was 102·4°, and at 6 P.M. was 105·4°. The same treatment was adopted as on the previous day and the result was similar. On the 26th there was evidence of consolidation over the whole of the right lower lobe and a patch of a similar character at the left base. The temperature rose as on the last two evenings and fell under the influence of the same treatment. 5 gr. of quinine were now ordered three times a day. The feeding and injections of strychnine were to be continued as before. On the 27th signs of improvement began to manifest themselves, the temperature being 101·4° at 8 A.M. and 103° at 6 P.M. The case now progressed favourably, the injections of strychnine being discontinued on the 29th and the temperature falling to normal for the first time on the 30th. A slight recrudescence of fever which occurred on April 4th was attributed to the regurgitation and inhalation of a portion of her food during her feeding on the previous evening. After this the temperature dropped steadily to normal, the recovery being uninterrupted, while the signs of consolidation which had involved the whole of

Digitized by Google

the two lower lobes had cleared up almost completely on April 10th. The patient is now much stouter than on admission and is in a condition of obstinate melancholia, refusing her food and having to be fed four times daily with the nasal tube.

The main point of interest in this case is the apparent proximity of death and the recovery under particularly unfavourable conditions. The patient was very much exhausted by her maniacal attack and added to our difficulties by her refusal of food, constant attempts to get out of bed, uncleanly habits, and violent resistance to anything done for her benefit or comfort. The irregularity of the temperature and the absence of a definite crisis are probably due to the pneumonia occurring as a complication of influenza. The effect of the strychnine injections upon the pulse was very marked as was also that of the quinine upon the high temperature. It is remarkable considering the severity of the fever that the patient was able to retain so large a quantity of food as was administered on each occasion through the nasal tube, the amount given altogether in the twenty-four hours consisting of 4 pints of milk, 6 eggs, and 6 ounces of brandy. To this somewhat unusual power of digestion the recovery of the patient is, no doubt, in great part due.

I am indebted to Dr. Tate for permission to publish this case.

Nottingham.

A CASE OF TEMPORO-SPHENOIDAL ABSCESS; TREPHINING; RECOVERY.[1]

BY HERBERT J. ROPER, M.R.C.S.ENG., L.R.C.P.LOND.;
AND
H. LITTLEWOOD, F.R.C.S. ENG.

A GIRL, aged fourteen years, had had a purulent discharge, which latterly had been offensive, from the left ear for two years. She came of an unhealthy stock, her father and mother being distinctly delicate and her grandmother showing scars all over her body the result of necrosis of bone, probably syphilitic. On June 11th, 1897, she complained of severe pain in the left ear and corresponding side of the head, which nothing appeared to alleviate. On the 13th the headache was still intense, but the earache had ceased. There was only a slight rise of temperature—generally about 101° F. On the 14th she was practically free from pain and on the following three days it was noticed that her memory was defective for common objects in the room. She was unable to name a spoon, fork, knife, chair, &c. As soon as the word was mentioned she recognised it and could pronounce it, but she forgot it again almost immediately. A slow pulse (50) and occasional vomiting were her other symptoms. On the 23rd her temperature was 101°, her pulse was 50, and her respirations were 12. She was drowsy and wished to be let alone. When roused she was childish in her manner and voice, quite different from her usual condition. She remembered dates well, but could not tell the name of any of the surrounding objects in the room. She had taken a dislike to many people of whom she had previously been fond and would have nothing to do with them. There was no disturbance of sensation or power of movement on either side. Optic neuritis was present on both sides. The ear was being carefully syringed with an antiseptic lotion and there was no discharge perceptible. The next day, however, the ear began to "run," but she was more drowsy than the day before, and the vomiting persisted and grew worse. On the 25th the temperature was normal, the pulse was still slow, but she was not so drowsy. During the day, though, the drowsiness increased and became more and more pronounced during the following three days until it resolved itself into coma. She took nourishment fairly well, retaining some. On the 27th and 28th she passed urine and fæces into the bed. The temperature continued normal. During the 29th the right arm became strongly flexed and remained motionless in that condition. On the 30th she was comatose but still able to swallow liquids; the right arm was paralysed and the right leg was much weaker than the left. I strongly advised operation at this stage, to which the parents readily consented. Mr. Littlewood at my request performed the operation. I administered ether, of which very little was required. Mr. Littlewood, assisted by Mr. F. E. Taylor, first exposed the mastoid process by a semilunar incision down to the bone and by chiselling opened the antrum until there was a free communication with the external auditory meatus. Some purulent material was found and the cavity was cleansed. He next dissected back a large semicircular flap and then proceeded to trephine over the petrous portion of the temporal bone. On pressing aside the dura mater the anterior surface of the petrous bone was well exposed but nothing was found here. The dura mater was perfectly healthy. Mr. Littlewood then proceeded to remove bone in a backward direction with Hoffmann's cutting forceps until he had exposed the membranes over the temporo-sphenoidal lobe. He then opened the dura mater and exposed the brain, which bulged out and did not pulsate. With a large trocar (Macewen's) he punctured the brain and immediately very offensive, thin, yellowish-green pus, with thick flakes of lymph floating in it, rushed out. The trocar was withdrawn and Mr. Littlewood plugged the opening with his finger in order to allow the pus to escape slowly, so that the intracranial pressure might not be too rapidly reduced. When the pus had all escaped the cavity began at once to shrink. This was then well washed out with boiled water by means of a syphon. Several large flakes of lymph came away with the water which returned. The large scalp-flap, which had become soiled by the discharge, was well washed with boiled water and afterwards with weak carbolic lotion. A drainage-tube was inserted into the abscess cavity and the flap was stitched up with silk sutures. The antrum was packed with iodoform gauze and a dressing of boric wool was applied over the whole. The condition of the patient at the end of the operation was wonderfully good; the extremities were warm and the pulse was 120 and fairly full. Before we left the house she moved her right arm. At 9.30 the patient was asking for food. Milk and soda-water in small quantities were given. On July 1st she had had a fairly good night. She moved her arm quite well and her mental condition was distinctly improved. Her temperature was normal and her pulse was 120. There was no pain. She asked for solid food. The dressing was changed. She had been asking her mother if the knocking had ceased, which appeared to refer to the chiselling. On the 2nd the temperature was subnormal. The patient was bright and cheerful but still amnesic. She took nourishment well. Hernia cerebri had formed. On the 4th the tube was removed and the scalp wound had nearly healed. The hernia continued to increase in size for some days until it was of the size of a Tangerine orange, when it slowly began to shrink. On the 22nd she sat up for a short time daily and was able to read and remember names of objects much better, though she still made mistakes. The antrum was filling up. Pressure was applied to the hernia after a time by means of a piece of thin sheet lead shaped to the hernial protrusion. After this it rapidly decreased in size and towards the end of September disappeared altogether and the wound healed over. The patient's memory gradually improved and now is almost normal. At the present date (March 10th, 1898) she is remarkably well in every respect.

Leeds

THREE CASES OF MYOMATA OF THE UTERUS COMPLICATING PREGNANCY;

PAN-HYSTERECTOMY PERFORMED IN TWO CASES AND SUBPERITONEAL HYSTERECTOMY IN THE THIRD; RECOVERY IN EACH CASE.

BY FRED. BOWREMAN JESSETT, F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL AND TO THE GORDON HOSPITAL FOR FISTULA.

I VENTURE to record these three cases because cases of myomata of the uterus complicating pregnancy are of comparatively rare occurrence and when met with, owing to the rapid growth which the myomata take and the symptoms they produce, are a source of grave anxiety to the medical

Digitized by Google

attendant and of danger to the patient. Abortion not unfrequently occurs, when the risk of septic poisoning and hæmorrhage is very great owing to the myomata interfering with the proper contraction of the uterus.

CASE 1. *Large fibro-myoma of the uterus complicated with pregnancy; pan-hysterectomy; recovery.*—The patient was a woman, aged forty years, who had been married for twenty years. She had had no family and no miscarriages and had always been quite regular, but there was no menorrhagia. She was a stout, healthy-looking woman and had always enjoyed good health. She consulted me on July 15th, 1894, with the history that she had about two months previously noticed a lump in her abdomen, which had of late increased very rapidly in size. She had had amenorrhœa for the last three months. The breasts were somewhat full with pigmented areolæ. She complained of a good deal of pain over the tumour. In the abdomen a hard rounded tumour was readily felt, which reached as high as the umbilicus; springing from this tumour another boss was felt on the left side. By bimanual examination these tumours were found to be connected with the uterus. As there were no urgent symptoms and as there was a question as to her being pregnant, she was advised to wait and report herself again in a month's time. On August 10th her husband called to see me, saying that his wife had been very seriously ill and that Mr. W. Newbery, her medical man, was very anxious respecting her condition. She had had high temperature and one or two rigors. I gave an order of admission into the Cancer Hospital. On admission the patient was very collapsed and in great pain. She had had a slight rigor and was sweating a great deal. The tumour had increased considerably in size, reaching some two or three inches above the umbilicus. Fœtal souffle could not be heard. *Per vaginam* the os could be reached with difficulty. The patient was placed in bed and was kept perfectly quiet for two days. She had no more rigors. Her night temperature reached 102° F. and she was obviously getting worse. On August 14th, under ether, with the assistance of Mr. Cotterell, I proceeded to operate. A long incision was necessary, extending for two inches above the umbilicus. The tumour was then expressed and the broad ligaments with the ovarian and uterine arteries were tied. The anterior and posterior flaps of the peritoneum were reflected. A large speculum was introduced into the vagina and the peritoneal flaps were reflected quite down to the vaginal roof, which was divided anteriorly and posteriorly. A ligature was applied to the two lateral undivided portions, the tissues were cut through, and the uterus with its myomata lifted out. All the ligatures were left long and drawn down through the vagina. Sutures were then passed through the peritoneal flaps and formed into long loops which were also passed out through the vagina. By this manœuvre the flaps were brought down in such a manner as to cause the peritoneal flaps to be in accurate apposition. The toilet of the peritoneum was attended to and the abdominal wound closed by single silkworm gut sutures passing through the whole thickness of the parietes. The patient made an uninterrupted recovery and was discharged from the hospital on Sept. 15th, just a month after the operation, she having been up for ten days before. On examination of the tumour a soft elastic prominence was felt in the posterior surface. On cutting into this a fœtus was discovered which had apparently been dead for some days.

CASE 2. *Large fibro-myomata of the uterus complicated with pregnancy; pan-hysterectomy; recovery.*—The patient was a woman, aged thirty-seven years. She had one child ten years old; she had had none since and no miscarriages. She had had amenorrhœa for four months. Mr. E. Bellis was sent for to see the patient in the middle of March. She was then suffering from most distressing vomiting. On examination he found a large tumour occupying the abdomen which had increased very rapidly of late. She believed herself to be pregnant, a belief which Mr. Bellis confirmed. The size of the tumour, however, clearly pointed to its existing apart from pregnancy. The patient suffered much pain from the pressure of the tumour and from the irritation to the bladder. I saw the patient with Mr. Bellis on March 21st, 1897. I found a large, smooth tumour extending some 2 in. above the umbilicus and situated to the left of the middle line. *Per vaginam* another growth was felt in the pouch of Douglas, pushing down the posterior fornix. It was with great difficulty that the os could be felt, situated high up in front of the last-named growth. The vagina was filled with a dark grumous fluid of the colour of coffee grounds, evidently blood-stained, which was escaping from the os. The discharge had a faint disagreeable smell. By auscultation over the abdomen the fœtal bruit was thought to be heard at a spot between the large tumour in the abdomen and the vaginal tumour. The question of treatment was discussed, and in view of the difficulty of reaching the os and the extremely high rate of mortality attending attempts at abortion I decided to negative this form of treatment. Next the question of leaving things as they were and awaiting further developments was discussed; this also was thought to be inadvisable owing to the reduced state of the patient, the pressure of the tumour upon the bladder, the possibility of the fœtus being dead, and, finally, owing to the large growth which existed in the posterior as well as in the anterior wall of the uterus, the chances of pregnancy extending to its full term being very remote, and the great danger to which the patient would be exposed if such a course were adopted. It was then decided to recommend the removal of the whole organ, my advice being strengthened by the good results which followed the operation in Case 1. The patient was admitted into a surgical home and with the assistance of Dr. Purcell and Mr. C. N. Barton, Mr. Bellis being present, I performed pan-hysterectomy on March 23rd. The patient made a perfectly good recovery and returned to her own home on April 19th. She has remained perfectly well since.

CASE 3. *Large fibro-myoma of the uterus complicated with pregnancy; the vagina filled by the tumour; subperitoneal hysterectomy; recovery.*—The patient was a married woman, aged thirty-nine years. She had had no children. She was sent to me by Dr. Macpherson Lawrie of Weymouth on April 20th, 1898, suffering from a large fibro-myoma of the uterus with suspected pregnancy of about from two to three months. She had been married for three years and had had no children or miscarriages. Menstruation, which commenced at the age of fourteen years, had always been regular but there was severe dysmenorrhœa; the last period was in the middle or at the end of January. The patient noticed that her abdomen was enlarging shortly after her marriage, but she had not suffered any inconvenience from it until a month previous to admission, when she had some difficulty in micturition. Since this time her urine had become very offensive and she could only pass it when lying down. The abdomen was felt to contain a large tumour which extended upwards to about 2 in. above the umbilicus. The upper part of the tumour was hard and resisting; the lower portion, which extended from the pubes to within an inch of the umbilicus, was soft and boggy; this portion appeared to be of about the size of a cocoanut. *Per vaginam* another tumour was found completely filling the pelvis; the uterus was drawn upwards and owing to this tumour it was impossible to feel the os. Bimanually this and the tumour in the abdomen were found to be connected, and the whole was firmly wedged into the pelvis and was very immobile. The bladder sound was passed with difficulty, and by it the soft, boggy tumour above the pubes was found to be the bladder. Auscultation revealed nothing. The urine was loaded with pus and contained some blood. The areolæ around the nipples were very slightly pigmented. After consultation it was decided to operate with a view of removing the entire mass. On April 23rd, the patient being placed under ether, I performed abdominal hysterectomy by the subperitoneal method. The patient made an uninterrupted recovery. The bladder at the time of the operation was found to be enormously thickened and dilated. On examination of the specimen the uterus was found to be strongly retroverted, the os being above the pubes, situated between the abdominal and vaginal tumours; the uterus was found enlarged and the walls somewhat soft and evidently contained a foreign substance. On cutting into the uterus a fœtus of about ten weeks was found.

Remarks.—I have reported these three cases, as they are, I think, of great practical importance. It is well known that fibromata often increase rapidly during pregnancy. This is more marked in the case of interstitial fibroids, single or multiple, with enormous thickening of the uterine tissue. This increase in size of the fibroids exaggerates the symptom of compression, to which it may have already given rise, and the pain resulting from the pressure upon the sacral plexus often is very intense. These symptoms are the more pronounced in the pelvic variety, when the fibroid develops below the brim of the pelvis, having its origin in the supravaginal portion of the cervix or lower part of the body of the uterus. In Case 3 such was the case and symptoms from compression upon the bladder, ureters, rectum, nerves, and

Digitized by Google

vessels were most formidable. Perhaps, however, the most common and by no means the least serious complication is abortion. Contraction of the uterus being hindered the danger of hæmorrhage and the risks of septic poisoning are very great. Lefour[1] out of 307 cases has collected 39 cases of abortion, in 14 of which the mother died. Nauss[2] out of 241 cases noted abortion in 47. The question of treatment in these cases must be decided by the nature of the accident and the seat of the tumour. Subserous fibroids of the fundus probably will in no way interfere with parturition and these cases not infrequently disappear after parturition. In these cases then the surgeon may wait, but in cases of pelvic fibromata the dangers are very much greater, although cases have gone their full time, and patients been delivered either naturally or artificially. The expectant treatment must not be therefore carried too far or in the endeavour to save the child one may lose both mother and child.

Some fibroids of the cervix may be enucleated either before or during delivery. Duyan[3] removed one which weighed 650 grammes. Braxton Hicks[4] obtained enucleation immediately upon the application of the forceps and delivery was completed without difficulty. Maundé[5] recommends enucleation by the vagina whenever that is possible. Out of 16 cases which he relates the mother only succumbed twice and the majority of the children were born alive. In the case of interstitial fibroids with abdominal development the operation for their removal is so serious and the risks of primary abortion are so great that it becomes a very serious question with the surgeon what form of treatment to recommend. He must not, however, ignore the fact that induced abortion and induced premature labour themselves present serious danger. When the placenta is inserted at the region of the tumour alarming hæmorrhage will ensue owing to the inability of the uterus to contract, not only so, but the patient is exposed to far greater risks of septicæmia. Lefour in a series of 23 cases of induced labour noted 3 deaths. Tarnier out of 7 cases in which labour was normal saw the mother die in 1 case and the child in 3. Out of 6 cases which were delivered by forceps 4 mothers and 4 children died. In 6 cases where version was performed 3 mothers and 3 children died. Süsserot out of 147 cases of pregnancy complicated by fibroma which he has collected says that the forceps were applied in 20 with the result that 8 mothers and 13 children succumbed; version was performed in 20 cases, when 12 mothers and 17 children died; in 21 cases the placenta was artificially extruded and in 13 of these the mothers died. Collectively the mortality of the mothers was 53 per cent., that of the children 66 per cent. Lastly, as Pozzi has pointed out, abortion liberates the compressed organs only to a very slight extent, and if the surgeon is afterwards obliged to resort to hysterectomy he has put himself in the position of having exposed the life of the patient twice instead of once. For these reasons it is manifest that the surgeon should decide upon early interference and when comparing the mortality after pan-hysterectomy or subperitoneal hysterectomy with those of induced abortion or premature labour the statistics are so much in favour of the former form of treatment that I consider the surgeon should not hesitate to recommend hysterectomy in all those cases in which the symptoms are such that surgical interference is imperatively indicated.

BRISTOL ROYAL INFIRMARY.—The Greig Smith Memorial operation theatre of the Bristol Royal Infirmary will be opened by Sir William Mac Cormac, the President of the Royal College of Surgeons of England, on Friday, Sept. 30th.

NEW LUNATIC ASYLUM.—At a special meeting of the Breconshire County Council held on Sept. 16th it was decided to erect a joint asylum for Breconshire and Radnorshire. The council resolved that the asylum should accommodate 350 patients, with administration for 500.

A PROTEST AGAINST THE PRESENT DAY TEACHING OF APPLYING THE BLADES OF THE OBSTETRIC FORCEPS WITH EXCLUSIVE REFERENCE TO THE TRANSVERSE DIAMETER OF THE MATERNAL PELVIS.

BY J. M. MUNRO KERR, M.B., C.M., F.F.P.S. GLASG.,
ASSISTANT TO THE CHAIR OF MIDWIFERY AND DISEASES OF WOMEN, GLASGOW UNIVERSITY; ASSISTANT PHYSICIAN TO THE MATERNITY HOSPITAL; DISPENSARY PHYSICIAN FOR DISEASES OF WOMEN, WESTERN INFIRMARY, GLASGOW.

As the report in THE LANCET[1] of my remarks in the discussion on "The Use and Abuse of the Midwifery Forceps" at the recent meeting of the British Medical Association in Edinburgh requires a little elucidation, and as the matter I referred to there is, in my opinion, of some importance, I desire to supplement what I said by the following paper. I there, as I do now, took exception to the general teaching of the present day in this country that, so long as the blades of the forceps are applied transversely as regards the maternal pelvis it does not matter, or at least it need not be considered, how they are disposed as regards the head of the child. This is a departure (a Continental importation) from the older teaching of obstetricians in this country, who from Smellie's time until quite recently laid great stress upon the importance of applying the blades, both of the straight and double-curved forceps, with a due consideration not only of the pelvis, but also of the diameters of the fœtal head. The present day teaching is without doubt largely due to the writings of Dr. Barnes, who in his "Lectures on Obstetric Operations"[2] maintains that while with the straight forceps "the head determines the manner of applying it," continues, "but with the long forceps it is the pelvis that rules the application. The position of the head may be practically disregarded." We, of course, are only concerned here with the double-curved forceps.

Writing on the application of the forceps, Dr. Playfair and Dr. Galabin, in their respective text-books on midwifery, express themselves as follows. I quote from them because their text-books are the two most popular in the various medical schools of this country. Dr. Playfair writes:[3] "It is admitted that in the high forceps operation the blades must be introduced in the transverse diameter of the pelvis without relation to the position of the head."

Dr. Galabin writes:[4] "Accordingly it is now the usual plan, even if straight forceps are used, not to pay much regard to the position of the head, but apply the blades one at each side of the pelvis." "In the case of the long curved forceps it is generally taught that the blades should be applied at the sides of the pelvis without regard to the position of the head. The position of the head should, however, be exactly determined in the first instance, not so much that any great difference in the position of the blades should be aimed at in consequence, but rather that," &c.

It may be taken, then, from these quotations that the general teaching and practice in this country in applying forceps is to consider only the pelvis of the mother and to apply the blades always in the transverse diameter. Now, I consider such teaching unwise and incorrect. It is unwise because it tends to encourage carelessness from its lack of exactness. In applying the blades of the forceps both the child's head and the pelvis of the mother should be considered, and when an operator commences to exert traction not only should he know how the blades are lying with regard to the maternal pelvis, but also how they are lying with regard to the head of the child. It is also incorrect.

Dr Playfair says,[5] speaking in vindication of the teaching of applying the blades of the forceps always in the transverse diameter of the maternal pelvis, that he agrees with Dr. Barnes, who points out that "do what we will and attempt

Digitized by Google

as we may to pass the blades in relation to the child's head they find their way to the sides of the pelvis." I presume Dr. Playfair means by "sides of the pelvis" the "transverse diameter" of the pelvis, for otherwise there is no sense in the sentence, seeing that the blades can only lie one to one side and the other to the other side. But such a statement as the above—and please observe it is a very generally expressed one—is, if one only thinks of it for a moment, tantamount to saying that the forceps is an instrument over which we have not complete control; that one operator will grasp the head as well as another; that all the operator has got to do is to introduce one blade to one side and the other to the other side of the pelvis, when the blades pass beyond his control and adjust themselves to the fœtal head in the best direction possible. But further proof of the incorrectness of the statement and general teaching will be found clinically. It will, I think, be admitted by all who have had much experience in obstetric practice that a head which was causing very great difficulty in extraction may sometimes be easily delivered by altering the grasp of the forceps. Now that is not because with the previous grasp the operator was exerting traction in a wrong direction, for before readjusting the instrument every operator would make attempts at traction in every possible direction. Neither is it because, on the first occasion, the blades of the forceps were not applied in the transverse diameter of the pelvis. The reason is simply that certain grasps of the head are better than others. In each case there is one grasp better and safer for mother and child than all others. The better grasp, however, is not likely to be secured by applying the blades of the forceps to the sides of the pelvis, and trusting to the chance of their adapting themselves to the most favourable diameter of the head. Much more likely is it to be obtained by applying the blades in a certain diameter of the child's head, which after due consideration of the case the operator believes to be the best.

Now a word or two with regard to the application of the forceps at the outlet, at the brim, and in flat pelves.

1. *At the outlet.*—Here, the long axis of the head having rotated into the conjugate diameter of the pelvis, the blades can as easily be applied with reference to the diameters of the fœtal head as with reference to the diameters of the maternal pelvis. When straight forceps were in use for this operation they were always applied with reference to the child's head and Dr. Barnes still recommends that method of applying them, as may be seen from the quotation I have already given.

2. *At the brim.*—Here, in spite of all one's efforts, it is nearly always impossible to grasp the fœtal head bi-parietally. The grasp must be more or less oblique in most cases. What I maintain, however, is that by considering the fœtal head and applying the blades deliberately to it as nearly as possible in the bi-parietal diameter a less oblique grasp is obtained one which will less often slip and one which will require less frequently to be altered than if the blades as recommended are simply introduced into the transverse diameter of the pelvis, traction exerted, and the grasp of the head never considered.

3. *In flat pelves.*—In such cases it is of the very highest importance that the fœtal head be deliberately grasped. In flat pelves, when the long axis of the fœtal head lies very nearly in the transverse diameter of the pelvis, the application of the blades of the forceps in the transverse diameter of the pelvis without reference to the head results in one of the three following grasps: (*a*) the head is grasped directly in the antero-posterior diameter—a very rare occurrence; (*b*) it is grasped very nearly but not quite in the antero-posterior diameter, also a rare occurrence; in such cases there is often the mark of the tip of one blade just above the eye; and (*c*) the head is grasped quite obliquely, one blade is to the side of the occiput and the other blade to the side of the forehead. This is by far the most usual grasp obtained.

What I maintain here is that if one applies the blades of the forceps, as is now generally taught, one cannot tell which of the above three grasps of the head one will get; it is entirely a matter of chance as far as the operator is concerned. Surely there is something wrong in a teaching into which the element of chance enters, especially when it is quite unnecessary that it should do so. To avoid it the operator has simply first to satisfy himself as to whether in a particular case it is better to grasp the head antero-posteriorly or obliquely and then deliberately to apply the blades to the child's head in the one or the other direction. That deliberate grasping of the child's head was the general teaching of obstetricians up till thirty years ago, only they, of course, approved only of the "oblique grasp," as they considered the antero-posterior one very dangerous to the child. Into the question of which of the two "grasps" is the better I will not enter at present. I would only say that in certain cases the one, and in certain cases the other, appears to me the safer for child and mother, and that the indications for the one or other will be found in the variety of flat pelvis one is dealing with.

In conclusion, I would only add that although the teaching I have been here condemning is very very general, I know it is not universal. Dr. Milne Murray, in his most able paper at the annual meeting of the British Medical Association the other day, referred to the matter and advocated a deliberate grasp of the head in flat pelvis, and other teachers in Edinburgh and elsewhere I am glad do the same.

Glasgow.

REMOVAL OF THE TRANSPARENT LENS FROM THE EYE IN HIGH DEGREES OF MYOPIA.

BY KENNETH SCOTT, M.B., C.M., F.R.C.S. EDIN.,
CLINICAL LECTURER ON OPHTHALMOLOGY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; OPHTHALMIC SURGEON, KASR-EL-AINI HOSPITAL, CAIRO.

THE true practical aspect of the operation of removal of the transparent lens for high degrees of myopia is apt to be somewhat lost sight of. On fully considering the question few surgeons can deny that in theory the above method of treatment is most excellent and should be adaptable with almost scientific exactitude—i.e., beyond a certain degree of myopic error removal of the lens from the eye by operation must be advocated in lieu of the more ordinary treatment by correction with spectacles. The much discussed point as to whether the operation tends to give rise to detachment of the retina or otherwise should for the moment be placed on one side and the question of lens extraction in high myopia be regarded from altogether a wider and more vital aspect. It is impossible to perform the operation of removal of the lens without in a certain degree violently disturbing the normal tranquillity of parts, the involved area comprising the ciliary zone and adjoining portions of the uveal tract, a region which, it is well known, is peculiarly liable to exhibit inflammatory resentment towards any extraneous interference. There are surely few ophthalmic surgeons who have not at some time encountered cases in which after extraction of a cataractous lens the eye has "gone wrong," either immediately after operation or later, without any apparent cause and in spite of every apparently possible precaution having been taken to avoid such a calamity. A myopic person and one with cataractous lenses cannot for one momen be classed in the same category. The latter is to all intents and purposes completely blind and has everything to gain by operative interference and nothing to lose should it prove unsuccessful, as he remains in very much the same plight as before. A myope, on the contrary, unless the case is one of malignant type, is a person who can generally obtain a reasonable amount of fairly accurate vision by the use of suitable spectacles, and who, if the operation proved only a partial failure, would be a considerable loser as regards vision, besides the possibility of noticeable eye deformity. In view of the inflammatory risks with their far-reaching consequences which the myopic patient would have to incur, quite apart from the possibility of the occurrence of retinal detachment, &c., the surgeon in the present state of our knowledge should wholly abstain from recommending the operation of removal of the lens in cases of high myopia. The method of treatment in question is one which is avowedly sound in theory and also quite feasible in practice, but it is absolutely imperative that it should be entirely regarded from the patient's point of view, and consequently should be placed in abeyance until the operation for the extraction of the lens from the eye by whatever method has been resolved into one which is entirely free from all risk of the onset of any after inflammation,

Digitized by Google

This accident is unfortunately not nearly so rare as one would wish, a fact which may be easily ascertained by reference to thoroughly complete and detailed lists of any moderately long series of cataract operation cases.

ST. THOMAS'S HOSPITAL.

A CASE OF GLANDERS; NECROPSY.

(Under the care of Dr. SHARKEY.)

GLANDERS is fortunately a fairly rare disease in the human subject, but it is probably not quite so rare as it is usually thought to be. The resemblance between the ulcer resulting from a broken-down farcy button and that caused by a gumma is very great, and as in the following case the ulcerations in glanders are very often thought at first to be syphilitic in origin. As gummatous ulcers are very much the more common it is only natural that the mistake in diagnosis should occur; but should the ulcer withstand energetic anti-syphilitic treatment a bacteriological examination may possibly prove of value. If the diagnosis of the superficial manifestations of glanders is far from easy, still more difficult is it to recognise its presence early when the disease attacks only or chiefly the internal organs. Some cases show many points of resemblance to enteric fever and in many the symptoms closely simulate those resulting from tubercle. No certain diagnosis can be made without a bacteriological examination and cultures, but these are so trustworthy and definite that the presence of glanders may sometimes be settled in a very short time. For the notes of the case we are indebted to Mr. H. H. Scott, house physician.

The patient, a man, aged thirty-two years, was admitted to the hospital on July 5th, 1898. There was nothing of importance in the family history; no tubercle or syphilis. With regard to the previous history, three months before admission the patient had suffered from what he called rheumatism, the symptoms being pain of a sharp, stabbing character, starting in the abdomen and shooting down the right thigh to the calf; the calf at the same time became swollen. The attacks of pain came on suddenly at intervals of from 10 to 15 minutes. He found that he obtained most relief by merely supporting the leg on pillows. He consulted a medical man, who gave him some medicine to take; this was followed by subsidence of the swelling in the calf; he also applied poultices and lotions to the abdomen at the seat of pain. He was laid up altogether for 24 days. On Feb. 17th last he attended the out-patient department of St. Thomas's Hospital and received treatment there for a period of six weeks. On referring to his out-patient's letter Mr. Scott found that his complaint was entered as periostitis of the right tibia, ? syphilitic. It considerably improved on iodide of potassium, but a month later (while still taking the iodide) there was the entry: "Sore on arm, ? gummatous"; he was treated with chlorinated soda lotion locally and the iodide of potassium was pushed to 20 grains three times daily; improvement resulted and the patient ceased to attend six weeks after his first appearance. In his work he had charge of one horse only and that was, he stated, perfectly healthy. For three months before admission he had been losing weight—he thought about 2 st. On June 21st, 1898—that is, 14 days before admission—the patient was troubled with pain in the right side of the chest and abdomen, this time of a heavy, aching character, but, as in his former illness, shooting down the leg at intervals of about 10 minutes. He stated that he only passed a small quantity of urine during the day, but it was of normal colour; there was no deposit and he had never had any pain on micturition. On admission the patient was found to be a moderately well-nourished man, with face flushed and eyes bright, complaining of abdominal pain, mainly referred to the epigastrium and the adjacent part of the right hypochondriac region. The abdomen was not distended; it moved well on respiration; to percussion the note was resonant everywhere; but even light percussion caused evident pain under the right costal margin in the right lumbar and upper part of the right iliac regions. The abdomen was held more rigid in these situations; gurgling was noticed in the right iliac fossa, but nothing abnormal was detected on palpation. The heart and lungs were normal. The liver edge was felt one finger's breadth below the right costal margin. Splenic dulness extended from the eighth rib above in the left mid-axillary line to just below the costal margin; laterally, it extended to the anterior and posterior axillary lines. It could be easily felt descending on inspiration; no pain was caused by palpation in this region. No spots in any way suggestive of enteric fever were to be seen. The pulse was 100 per minute, regular and of fair tension; the respirations were 24. The urine was normal, of 1020 specific gravity. Just below the bend of the elbow on the outer side of the right arm was a sore on a reddish base an inch to an inch and a half in diameter, practically healed; the patient described it as being a sort of boil. Shortly after admission the patient passed a motion, almost liquid, dark yellow in colour, and appearing to contain undigested milk. The serum reaction of typhoid fever was tried with negative result, there being no clumping or loss of motility in half an hour with a dilution of 1 in 10. Diazo-reaction also did not give any characteristic result. The temperature rose to 102° F. in the evening, but in the morning it fell to 99 8°. The patient slept and took food well. Next day he complained of pain in the hepatic and splenic regions on palpation but none now in the right lumbar or iliac regions. Pain in the epigastrium still continued and was increased on taking food. The patient had up to July 12th been kept on milk and beef-tea, but on that date he began to complain of such low diet; he was given bread and butter, milk puddings, and two eggs daily. The idea that the case was one of enteric fever had been by this time almost given up. The temperature varied between 102° in the evening and 97·4° in the morning. By July 13th the pain had gone from the abdomen except in the splenic region. The abdomen all this time had been too rigid for a good examination to be made and it was suggested that the patient should be examined under an anæsthetic, but the temperature suddenly fell to normal and remained so for twelve hours. The patient seemed much better, so an anæsthetic was not given, the general opinion being that the case was merely one of fever without explained cause and that all was going to clear up. After this the intermittent type of temperature again appeared (varying between the limits of 103° and normal), but, in spite of this, the patient stated that he felt well and wished to get up. Four days later he was examined under an anæsthetic but nothing wrong could be detected in the abdomen. On July 25th he complained of an aching pain in the right calf and on the right tibia just above the malleolus. There was nothing to be seen at either situation nor did movement cause any pain, but the spots were very tender and painful to the touch. At the angle of the scapula over the right lung breath-sounds were feeble and on deep inspiration a few crepitations of small and medium size could be heard. The lungs had been repeatedly examined in order to see if there were any signs of tubercle to account for the temperature, but nothing had been detected until that day. The pain above the ankle becoming greater Mr. Clutton was asked to see the case and in his opinion the painful spot suggested a localised periostitis following enteric fever. Widal's reaction was consequently again tried but with the same negative result as on the former occasion. Fomentations always relieved the pain. He also now began to complain of pain over the right eye, increased by pressure, and the spot was very tender. On July 29th similar pain was complained of in the left eye, knee and ankle; there was ptosis of the left eyelid and pain in the right eye was increasing; the fundi were found to be normal. The right side of the face and the right temporal fossa began to swell and pain was caused on moving the jaw. On August 2nd a small pustule was noticed at the summit of the swelling; the left eye was kept closed, was painful and suffused. The evening temperature had been rising during the last week and for the past three days had remained

Digitized by Google

during daytime also almost uniformly up to 103°. On the 3rd the face was very much swollen. Small red nodules were noticed in the following situations: on the right arm at the junction of the upper and middle-third of the ulna, over the styloid process of the radius, and on the left arm near the middle of the biceps muscle. All were very painful; the first two were of the size of a sixpence and the third was as large as a florin. The patient had been delirious in the evening for the last two days and was bathed in perspiration at varying intervals. On the 5th the three nodules mentioned were pustular and many more pustules with inflamed red bases had appeared (following small red raised nodules as before) all over the face and legs. They did not now, however, cause any pain; in fact, on this morning the patient lay in bed and read a newspaper. There was this day some yellowish, offensive, watery discharge from the nostrils. Towards afternoon he began to run rapidly downhill. He became very drowsy, the pulse was rapid and feeble, delirium was low and muttering with louder outbursts at intervals, and he could not be roused to reply to questions. Several pustules appeared yesterday over the swelling in the right temporal fossa and some of these had now run together forming an irregular shaped ulcer. The ulcers extended through the skin and subcutaneous tissue and had very defined edges, giving the appearance of having been punched out; they were somewhat suggestive of vaccination marks which had become purulent on an inflamed, swollen base, or of small-pox pustules except that they were not umbilicated. Elsewhere the pustules remained discrete. Over the soft palate and the nasal septum some half-dozen similar pustules were present. The patient sank rapidly and without again recovering consciousness. He died at 4.30 A.M. on August 6th.

Necropsy.—At the post-mortem examination several of the nodules mentioned were found to be in the skin, others were subcutaneous, and others were still deeper in the muscular tissue. The maxillary lymphatic glands were enlarged and slightly also the submaxillary glands. There were a few shallow ulcers in the stomach; the edges were not indurated. Studded over the lungs and close beneath the pleura were numerous nodules of about the size of a split pea or a little larger, greyish-white in colour; a few of them were soft and caseous, but mostly hard. The lung tissue itself seemed normal. The heart was normal. The spleen was large, but nothing abnormal was found in it. The liver, kidneys, and intestines (except the stomach) were normal. A culture was taken before death from one of the pustules on the swelling in the right temporal fossa. The growth on potato and the microscopical appearance of the bacillus were pronounced by Mr. Shattock to be characteristic of bacillus mallei. It was practically a pure culture. Pus taken post mortem from an intra-muscular abscess showed results equally typical.

Remarks by Mr. SCOTT.—As regards the treatment of the case nothing seemed in any way to affect the course of the disease. On admission the patient was given quininæ sulphas 1 gr., mistura potassæ citratis effervescens 1½ oz. three times a day. On July 20th, with a view to more effectually controlling the temperature, 5 gr. of quinine were given twice daily. This was equally without result, so on July 30th he was prescribed liquor hydrargyri perchloridi 1 drachm, potassii iodidum 10 gr., infusum gentianæ compositum to 1 oz. three times a day, again without effect. The difficulty in the case from the first was in the matter of diagnosis. The enlarged spleen, general malaise, and a moderately high temperature suggested enteric fever, but the result of the serum test was negative. As the case went on this idea was given up, for the temperature was very unlike typhoid fever at the beginning of the third week. The bowels were opened as a rule once daily and the stools after the first two or three days were normal. There was nothing in the history to point to any definite disease. On July 12th, as stated in the notes, the temperature fell and it was thought that all might go on well and the cause never be discovered. The improvement, however, only lasted a very short time, when the tender spot over the tibia appeared. The view that the case might turn out to be an anomalous form of typhoid fever now had to be again entertained, Mr. Clutton stating that the lesion suggested a post-enteric periostitis. Serum reaction, however, again negatived that view. A few days later the remittent form of temperature was strongly suggestive of pyæmia from some cause, but nothing could be discovered on close examination into his history or on physical examination. When on August 3rd the small, red, raised nodules later becoming pustular and the offensive nasal discharge appeared the idea that the case was one of glanders began to come to the front and a culture was accordingly taken which subsequently, but too late for anything to be undertaken in the way of treatment, proved to be an almost pure culture of bacillus mallei both microscopically and by the characteristic yellowish honey-like mass on potato becoming of a brownish chocolate colour. From consideration of evidence the case should probably not be looked upon as one of acute glanders, or more strictly subacute, with an exacerbation towards the end and running its course in from six to seven weeks, but as a chronic one lasting from four to five months, and in support of this view is the fact that the lymphatic glands of the arm and the submaxillary glands also were enlarged and hard, and again the lungs showed well-marked farcy nodules which in some instances could be shelled out from their bed of lung tissue beneath. Then probably the "sore on the arm," mentioned as occurring in March last while the patient was attending the out-patient department, was a chronic farcy lesion, although it certainly improved to some extent on administration of potassium iodide, or the improvement may have resulted from the local use of chlorinated soda lotion.

CUMBERLAND INFIRMARY.

A CASE OF SUPPURATIVE PERIOSTITIS OF THE NECK OF THE FEMUR WITH ACUTE PYÆMIA.

(Under the care of Mr. LEDIARD.)

FOR the notes of the case we are indebted to Dr. Stuart McDonald, house surgeon.

The patient, a boy, aged sixteen years, was admitted to the infirmary on August 8th, 1898, with the following history. Seven days before, while in the train on an excursion, he was seized with acute pain in the left groin. The pain was so severe that he could not walk about and on his return he had to be assisted home by friends. He was in perfect health in the morning and there had been no recent injury. On the following two days, the pain persisting, he kept in the house but was not confined to bed; the pain was relieved by turpentine and hot cloths. He felt hot and feverish at times, and on the Wednesday night, the third day from the beginning of his illness, he had a shiver and sweated profusely; he was also delirious that night. On the following afternoon he walked out and consulted a medical man in town, who found that he was suffering from severe pain in the upper part of the left thigh, which was slightly swollen; there was localised tenderness on pressure, below the middle of Poupart's ligament. There was no pain on "jarring" the hip-joint and no pain in any other part of the body. The boy walked very lame and only with assistance. His temperature was 102° F. He was sent home to bed and given anti-rheumatic remedies with hot poultices locally. On Friday and Saturday the symptoms continued, the temperature ranging between 101° and 103° and the swelling extending down the thigh. On the Sunday he complained for the first time of pain in his other joints, especially the right wrist, which was slightly swollen. On Monday there was dulness at the base of the right lung with friction. There was a trace of albumin in the urine. He was removed to the hospital in the afternoon. With regard to his personal and family history, the patient's mother was phthisical; the rest of the family were healthy, but the boy had always been delicate; he had only been laid up once, however—viz., with inflammation of the left lung seven years before. Six months ago he had been knocked down at football and had received a kick on the left hip. He was not laid up with this, but his father stated that he had seen him lately walking with his hand over the left hip. The boy himself did not complain. On admission the patient looked very ill. His temperature was 102°, his pulse was 125, and his respirations were 30. He could answer some questions but could not sustain attention. The tongue was dry and brown, the lips and teeth were covered with sordes, the bowels had not been moved for two days. As to the local condition, there was well-marked swelling of the whole of the left thigh, most marked in the upper part, where there was hard inflammatory œdema extending from below Poupart's ligament up into the left iliac fossa and out over the great trochanter and immediately above it over the ilium. There was a distinct dark blush

Digitized by Google

over this latter region and distension of veins over the upper and outer aspect of the thigh. There was acute tenderness over a small area below the middle of Poupart's ligament and also over the area of blush. There was no fluctuation to be made out anywhere. The right wrist was slightly swollen, but there was no redness. No other joint was affected. There was dulness at the base of the right lung with occasional harsh friction. The first sound was almost inaudible; there was no bruit or friction. There was a trace of albumin in the urine, the specific gravity of which was 1018. The patient was given two drachms of whisky hourly; he was very thirsty and took milk and soda freely. Mr. Lediard operated the night of admission about 8 o'clock. The temperature had then risen to 104°. An incision was made over the most prominent part of the swelling behind—viz., over the great trochanter and immediately above it. The incision extended down to the bone; the tissues, especially the edge of the fascia, presented an unhealthy gelatinous appearance. About half an ounce of rather watery pus was evacuated; it seemed to come from deep down just above the trochanter. Some seemed to come also from along the ilium, but the tissues were separated from the bone down to the margin of the sacro-sciatic notch, and no more was discovered. The wound was stuffed with iodoform gauze. The pus evacuated contained numerous micrococci, mostly in the form of diplococci, but there were also typical staphylococci. The patient stood the operation very well. Two hours afterwards the temperature had fallen to 102·5°, the pulse was 125, and the general condition remained unchanged. At 1.30 A.M. there was considerable oozing from the wound, which was dressed and more pressure applied; the patient was very restless, sweating profusely, and was very thirsty. The temperature was 103°, the pulse was 135, and the respirations were 35. On August 9th, at 9 A.M., the patient looked worse: the respirations were 42; the pulse was 140 and very weak; and the temperature had risen to 104°, with noisy delirium. 10 c.c. of anti-streptococcic serum were given. At noon the temperature had risen to 106°, and just before death, which took place at 3 P.M., it reached 108°.

Post-mortem appearances.—The incision in the thigh was prolonged up and down; the periosteum of the shaft was healthy. The periosteum of the neck of the femur was found to be thickened and dissected off the bone with pus all the way round. There were about two drachms of pus in the hip-joint and the head of the femur and lining of the acetabulum were of a bright pink colour; the interior of the head and neck of the bone and epiphyseal cartilage were apparently healthy. The right wrist-joint was opened and found to be apparently healthy. With regard to the lungs there was recent pleurisy over the lower and lateral aspect of the right lung and there were extensive old adhesions over the lower lobe on the left side. Both lungs were acutely congested. As to the heart, there were two minute patches of recently effused lymph on the surface of the right ventricle near the apex. There were no vegetations on the valves and the organ looked otherwise healthy. Both kidneys were congested and showed cloudy swelling. There was a small group of miliary abscesses deep in the cortex of the left kidney. The spleen was much enlarged, very soft and friable. A small superficial abscess containing about ten drops of pus was discovered in the scalp behind the right ear. Films were prepared from the pus from below the periosteum, from the hip-joint, from the pyæmic abscesses in the kidney, and from the scalp abscess. These all showed similar organisms—viz., micrococci, many diplococci and typical staphylococcal groups; there were no streptococci and no bacilli. Films from a scraping from the spleen and from blood from the interior of the heart showed similar forms, but in that from the blood in addition were numerous large bacilli like bacillus subtilis in appearance, probably post mortem putrefactive forms.

Remarks by Dr. MCDONALD.—It would be difficult to say what chances, if any, this patient would have had from early operation, the small amount of pus formed locally and the intensity of the general symptoms pointing to a very virulent type of staphylococcus. The relationship of the old injury of the hip to the illness is by no means clear and the significance of the scalp abscess is also doubtful. An eminent pathologist who examined the preparations was of opinion that it certainly had no causal connexion. With regard to the serum used the absence of streptococci from the first pus evacuated seemed to contra-indicate its use, but as the patient was rapidly getting worse the next morning it was decided to try it. It is impossible to say how much of the hyperpyrexia was due to its use, but it certainly seemed to hasten the end.

Reviews and Notices of Books.

Outlines of Medical Jurisprudence for India. By J. D. B. GRIBBLE, M.C.S. (retired), and PATRICK HEHIR, M.D., F.R.S. Edin., &c. Fourth edition, revised and corrected. Edited by Surgeon-Major PATRICK HEHIR. Madras: Higginbotham and Co. Calcutta: Thacker, Spink, and Co. Bombay: Thacker and Co. 1898. Pp. 498.

THE fact that this work has reached the fourth edition is proof that it supplies a want. One especial merit about the book is that it is equally suitable for members of the medical and the legal professions. All technical expressions are explained in footnotes, so that a barrister consulting it would be able to understand the purely medical details. The whole book is arranged in numbered paragraphs, so as to be easy of reference.

With the exception of minor changes, including that of correction and revision, no noteworthy modification has been made in this edition, and its publication was delayed owing to the editor being on duty with the Tirah Expedition. The text contains a large number of illustrative cases, the majority of them culled from Indian experiences, so that they are new to English readers; several well-known examples, however, are copied from the English text-books.

The chapter on Evidence in India is particularly interesting. It would seem from this work that the great difficulty with which all magisterial and judicial officers in India have to contend is the false evidence which daily comes before them. The editor thinks that it is no exaggeration to say that a case scarcely ever comes before a criminal court in which there is not a certain amount of false or concocted evidence. The duty of a judge or magistrate in India is, generally speaking, not so much to decide which story is the true one and which is the false one, but to separate the falsehood and the truth on both sides, and, having eliminated the former, to decide upon the case. The legal maxim, *falsum in uno, falsum in omnibus*, does not apparently apply in that country. In England the discovery that some evidence for the prosecution had clearly been concocted would probably be quite sufficient to ensure the release of the accused; but if such a rule were to be followed in India the author is of opinion that there would scarcely ever be a conviction.

The book is well printed and, owing to the marginal notes on nearly every page, very easy of reference for barristers and medical men.

Laboratory Work in Physiological Chemistry. By FREDERICK G. NOVY, Sc.D., M.D., Junior Professor of Hygiene and Physiological Chemistry, University of Michigan. Second Edition. Revised and Enlarged. Ann Arbor, Michigan: George Warr, Publisher. 1898. Price $2.

THE system of orthography adopted by so many scientific American writers is apparently ignored in this volume except in regard to a few everyday words such as "color" and "behavior." But we do not find the final "e" lopped off such words as oxide, chlorine, urine, as is so conspicuously the case in many American text-books of science. The work before us is essentially a laboratory companion, and calculated to train the student in the right way, that is to develop his capacity of observing and reasoning. The plan adopted is clear and simple and for an experimental course the best. Thus the chemistry and physiology of food stuffs, of the animal fluids and secretions, is first presented, and then succeed short paragraphs describing the reactions characteristic of the substance under study. When it is a factor

Digitized by Google

of pathological importance processes are also given for the quantitative determination of certain constituents, as, for example, uric acid in urine, hæmoglobin in blood, and so on. We have often pointed out that the original test devised by Pettenkofer for biliary acids is not satisfactory when, as is enjoined in the volume before us, cane sugar is employed; it is much better to substitute glucose which does not char and mask the violet colouration. The tintometer of Lovibond has evidently not come into use in America in its application to "hæmoglobinimetry," for we do not find this ingenious and useful apparatus described in the chapter (VIII.) on blood. The author recommends the bibulous paper method for estimating the fat in milk. This method, it is true, is very accurate, but there are other methods equally accurate and certainly much less laborious, as for example the Werner Schmid method, or the Leffman Beam centrifugal process, which by the way had its origin in the United States. In the now well-known Kjeldahl process for the estimation of organic nitrogen the addition of permanganate to the hot acid fluid is suggested. Investigators in this country have found that this leads to a loss of nitrogen, and consequently the modification has been abandoned, and when potassium sulphate and a pellet of mercury are employed it is not necessary in order to make the digestion and change to a colourless fluid complete. The book concludes with an excellent scheme for the the examination of urine, and some microscopical illustrations of urinary sediments.

Conservative Gynæcology and Electro-Therapeutics. By G. BELTON MASSEY, M.D. Third edition. Illustrated. Pp. 390. 1898. Philadelphia: The F. A. Davis Co.

IT is quite certain that electricity judiciously used is capable of giving good results in certain classes of gynæcological cases, and the numerous observations of Apostoli, Keith, and others show that it has in many cases a very definite effect upon the growth of fibroid tumours of the uterus. It is of great importance, if this method of treatment be used at all, that it should be used in properly selected cases, and with a due knowledge of what may be expected from it, and how the best results are to be obtained. There can be little doubt but that the disappointments and failures that have occurred are due to the want of a proper knowledge of the best methods to be employed, and to an absence of that technical knowledge which is so indispensable if really trustworthy results are to be obtained. In his book upon Conservative Gynæcology and Electro-Therapeutics Dr. Massey, who is an ardent advocate of electrical treatment in gynæcology, gives a clear account of the subject and shows what may be done by this method of treatment. The book consists of two parts. The first part contains, amongst others, chapters upon the Phenomena attending the Transmission of Galvanic Currents through Living Bodies, the Typical Methods of applying Electric Currents in the Diseases of Women, and an account of the various affections in which the author recommends their use. It is clearly in the selection of cases suitable for this treatment that great differences of opinion may arise. No doubt all would admit that cases of endometritis, chronic metritis, fibromata of the uterus, and inflammatory exudations in the pelvis, are likely to be benefited by the treatment. In cases of early ectopic gestation, however, most gynæcologists would prefer to rely upon operative treatment, and yet the results brought forward by the author tend to show that electrical treatment in such cases may be followed by good results and is seldom productive of any harm. The use of the faradaic current is recommended in labour in cases of inertia uteri and for post-partum hæmorrhage, for which Dr. Massey says "there is nothing equal in immediate results to the primary faradaic current applied with a bipolar electrode within the uterus, or a single active pole in that situation and the other on the abdomen." Here most obstetricians would be inclined to join issue with him and to continue to rely upon the tried and known effects of an intrauterine injection of hot water. Still, if the necessary apparatus were at hand, no doubt good results could be obtained with the faradaic current.

The second part of the book contains a clear account of the rudiments of medical electricity, and there are two appendices, one containing a table of 86 cases of fibromata of the uterus with details of treatment and ultimate results, and the second a table of 34 cases of catarrhal disease of the uterus under electric treatment.

Lehrbuch der Anorganischen Chemie. Von Professor H. ERDMANN in Halle. Mit 276 Abbildungen und 4 farbigen Tafeln. Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn. 1898. (Manual of Inorganic Chemistry. By Professor H. Erdmann. With 276 Illustrations and 4 Coloured Plates.) Price 18 marks.

THERE is considerable difference of opinion amongst English teachers of chemistry as to whether the purely mathematical portion of the science should be presented to the student before he has made a few experiments, before he has handled a test-tube, blowpipe or reagent, or, in other words, before he has got a glimpse of the nature of chemical change. If the student is an absolute stranger to the elements of the science there can be no question as to the way in which he should start. The volume before us is therefore adapted for those students who already possess some knowledge of chemistry such as now may be gained at our schools, since the author with startling suddenness opens boldly with the consideration of the theoretical side of the science in a chapter on decimal fractions and the use and value of logarithms. This section amounts, indeed, to a plea for the more general employment of logarithms in calculation, and a loose sheet of logarithms useful in chemical calculations is placed under a band on the inside of one of the covers. Next we come to theory and law, atomic and molecular weights, and the methods for their determination, the first chapter closing with valency and affinity. The second chapter, which we should ask the beginner to study first, is devoted to what the author calls "the metalloids," under which heading he includes the ordinary non-metallic elements, and under the same classification selenium, tellurium, arsenic, antimony, silica, and germanium. Under the class entitled "*edelgase*" (rare gases) occurs an excellent section on argon and helion. The apparatus used in the preparation and separation of these gases is fully illustrated, and an admirably coloured map of the spectra of gases includes the brilliantly characteristic lines of these newly discovered elements. For the rest, the plan of the book is much on the same lines as English text-books, the classification adopted being already indicated, the elements being divided into metalloids and metals (*Metalloide und Metalle*). We are glad to find that an acknowledgement is made of the work of the English chemist, Mr. J. A. R. Newlands (whose death, we regret to add, was announced a short while ago), in connexion with the discovery of the periodic law afterwards so ingeniously elaborated by Mendelèeff, the illustrious Russian chemist. The book will be very useful as an introductory manual for students taking the more purely technical sides of the science, since the description of technical processes, of metallurgical processes, of the refinement of metals, and of the compression of gases is given in some detail, and, moreover, in accordance with modern advance, the preparation of aluminium from cryolite or clay is here included; indeed, the author has treated the subject

Digitized by Google

with a surprising completeness of detail and narrative considering the limits of space entailed in a "*lehrbuch*."

Responsible or Irresponsible? Criminal or Mentally Diseased? A Plea for the Unjustly Convicted, and on the Cause of Crime. By HENRY SMITH, M.D. Jena. London: Watts and Co. 1898. Pp. 92. Price 1*s*.

THE intention with which this little book is written is well expressed in the opening words of the preface. "I plead that our fellow-citizens who are of unsound mind shall not be treated as criminals; and that those who may have broken a law or committed a crime when in a morally unconscious state, the result of disease, shall not be convicted as insane or as criminals, but shall be treated as persons diseased, and neither consigned to a convict prison nor to a lunatic asylum, but to an asylum fitted for those who require medical attention."

Most people will probably agree with Dr. Henry Smith in the general sense of the above, but when details are discussed a number of difficulties will be found. In the first place the law does not define what insanity is; it is a matter of evidence, expert or otherwise, whether a person is insane or not, and therefore it is of the first importance that medical men should know what insanity is, and when a person is insane. Do they know? Are they agreed on this difficult question? Dr. Smith thinks not; and there is certainly great room for opinion. Another difficulty is that a medical man finds it by no means an easy matter to convince a patient that it is no more disgraceful to be sent to a home for the cure of dipsomania, delirum tremens, or mania, than to a hospital for the cure of fever or small-pox. Such patients naturally shrink from letting the world know the true diagnosis of their condition, but all the same it is universally admitted amongst medical men that some radical change in the laws relating to inebriety is required if practitioners are to do justice to their patients. Dr. Smith enters fully into this question and his remarks thereon are well worth perusal. He maintains that magistrates should have the power to commit drunkards to a home or asylum where they may be detained till cured of their desire for drink.

Another chapter which may be more noticed in legal circles than in medical is entitled "Equal Means must be given to all Men for their Defence." Here the author makes declarations with which we cannot agree. "I venture to say it is all but certain that he who can pay for a costly and learned defence will be discharged and the poor man who cannot pay will be convicted." We believe that such is by no means the case. If a prisoner is undefended by counsel the judge gives him every assistance in his power; if the charge is very serious a barrister is requested to undertake his defence.

This little volume is certainly worth reading and we trust that many of the reforms which its author suggests will eventually be carried out.

JOURNALS AND REVIEWS.

Annales de Gynécologie et d'Obstétrique. August, 1898. Paris: G. Steinheil.—Professor Pinard contributes a note to this number of the *Annales* upon Puériculture during Pregnancy, with special reference to the influence of the well-being of the mother upon the development of the fœtus. Professor Vautrin writes upon Gangrene of Interstitial Fibroids of the Uterus; and Dr. Meslay and Dr. Hyenne conclude their paper upon Degenerative Changes in Fibroid Tumours of the Uterus. Dr. Hartmann contributes an article upon Posterior Colpotomy in the treatment of Suppurating Appendages. Dr. Labusquière reviews recent papers by Dr. Grigorieff and Dr. Knauer upon the Transplantation of Ovaries and its results, and a paper by Dr. Karl Heil upon the Existence of a Physiological Slowing of the Pulse in the Puerperium. The treatment of Chronic Bartholinitis is considered by M. Cordier, who recommends the injection into the gland of a saturated alcoholic solution of salicylic acid. The rest of the number consists of the proceedings of the Society of Surgery and the Obstetrical and Gynæcological Society of Paris.

Revue de Gynécologie et de Chirurgie Abdominale. No. 4. July–August, 1898. Paris: Masson et Cie.—As usual this review contains several articles of great value. Tuffier writes upon Vaginal Hysterectomy without Forceps or Ligatures. He employs an instrument he calls an angiotribe with which he crushes the broad ligaments and so occludes the vessels. F. L. Neugebauer gives an interesting account of all the recorded cases—some 31—of utero-intestinal fistulæ with full details of the cases and a table. Two cases of abdominal hysterectomy for fibromata of the uterus complicated by pregnancy at full term are related by Eugène Gutierrez. Henrotin and Herzog describe 2 cases of extra-uterine gestation, the one occurring in the extremity of an accessory pavilion of the Fallopian tube, the other in a diverticulum. These are of great interest in connexion with early rupture of ectopic gestations. In an article upon the therapeutic value of ovarian extract Jayle concludes that it is often useful and recommends it in cases of removal of the ovaries, at the menopause, in amenorrhœa, dysmenorrhœa, chlorosis, and ovaritis. Ratchynsky, reviewing the various forms of suturing the abdominal wall after laparotomy, recommends deep sutures embracing all the structures, with separate suturing of the aponeurosis of the recti and superficial sutures for the skin. The number also contains a paper illustrated by cases upon lateral implantation of the intestine by Lauwers, and the usual analysis of current literature.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. New Series, Vol. XLI., Part 2. June, 1898. London: J. & A. Churchill. Price 10*s*.—This part contains the following memoirs: 1. The Segmentation of the Ovum of the Sheep, with Observations on the Hypothesis of a Hypoblastic Origin for the Trophoblast, by Richard Assheton, M.A. With 4 plates. 2. On the Heart-body and Cœlomic Fluid of Certain Polychæta, by Lionel James Picton, M.A. With 4 plates. 3. On the Hypothesis that Lake Tanganyika Represents an Old Jurassic Sea, by J. E. S. Moore. With a plate. 4. On the Reno-pericardial Canals in Patella, by Edwin S. Goodrich, B.A. With a plate.

The Journal of Anatomy and Physiology. Conducted by Professor Sir WM. TURNER, Professor D. J. CUNNINGHAM, Professor A. MACALISTER, Professor J. G. MCKENDRICK, and Professor G. D. THANE. Vol. XXXII., Part 4. July, 1898. With Plates and Figures in the Text. London: Charles Griffin and Co. Price 6*s*.—This part contains the following articles: 1. Dr. W. G. Aitchison Robertson: The Salivary Digestion of Starch in Simple and Mixed Diets. This article is noticed in an annotation in our present issue. 2. Mr. J. Playfair McMurrich, M.A., Ph.D.: A Case of Crossed Dystopia of the Kidney with Fusion. 3. Mr. N. Bishop Harman: The Duodeno-jejunal Flexure, its Variations and their Significance. 4. Louis J. Mitchell, M.D.: Notes on a Series of Thirty-nine Cases of Meckel's Diverticulum. 5. Dr. Francis O. Simpson: Congenital Abnormalities of the Heart in the Insane. 6. Mr. A. E. Taylor: Note on a Case of Six Lumbar Vertebræ and Abnormal Middle Sacral Artery. 7. Dr. F. W. Eurich: Contributions to the Comparative Anatomy of the Neuroglia, with two plates. 8. Dr. R. Broom: On the Organ of Jacobson in the Hyrax, with a plate. 9. Dr. R. Broom: Is there a Critical Period in Marsupial Development? 10. Mr. F. G.

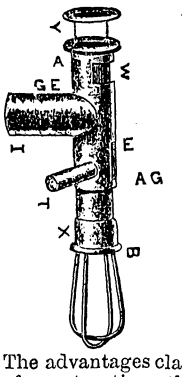
Digitized by Google

Parsons: The Muscles of Mammals, with special relation to Human Myology. 11. Mr. J. H. F. Wilgress of Selwyn College, Cambridge: A Note on Hereditary Stiffness of the Metacarpo-phalangeal Joint of the Thumb. 12. Dr. Edred Corner of Sidney Sussex College, Cambridge: On Some Skulls from Ceylon. 13. Professor Richard J. Anderson: Some Notes on the Manus of the Dugong. 14. Dr. Edward Fawcett: Some Points concerning the Mounting of Dissections in Basins. 15. Archæologia Anatomica. 16. Mr. R. J. McClelland (student): Note on a Moderator Band in the Left Ventricle and a Perforate Septum Ovale in the Heart of a Sheep. 17. Professor Bertram C. A. Windle: Eighth Report on Recent Teratological Literature. Lastly, there are notices of new books, a report on the Association of American Anatomists, and the index to Vol. XXXII. of the journal.

Medical Temperance Review.—The September number contains an abstract of a paper on Alcohol in Drugs and Drug Preparations read by Dr. Norman Kerr at the meeting of the British Medical Association. There is also an account of the proceedings at the annual medical temperance breakfast which took place in Edinburgh during the meeting of the Association. The speakers were Professor Simpson, Dr. ims Woodhead, Dr. Clouston, Dr. Ridge, Dr. Connel, and Mr. A. P. Young.

Liverpool Medico-Chirurgical Journal.—The original articles are on Colotomy (by Mr. F. T. Paul), on the Influence of Skin Condition on Surgical Procedure and on the Treatment of Eczema by Counter-irritation (by Mr. Colin Campbell), on Sewage Disposal (by Dr. H. R. Jones and Dr. Frank Robinson), on Foreign Bodies and the Use of the x Rays (by Mr. C. T. Holland), on Practical Gynæcology (by Dr. William Alexander), and on Cholecystitis as a Complication of Enteric Fever (by Dr. C. A. Hill). As usual the bulk of the journal consists of reports of the meetings of the Liverpool Medical Institution.

Mercy and Truth.—The numerous articles include an account of the Kashmir State Leper Hospital, by Dr. E. F. Neve. There is a full-page photo-print of a Chinese Opium Smoker.



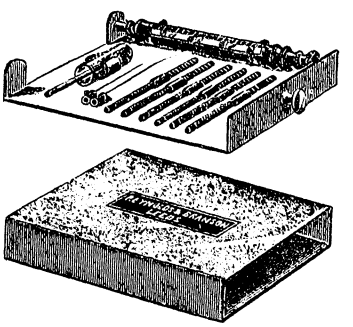
In the *Phonographic Record* for September contributions by Sir W. R. Gowers on Syphilitic Disease of the Cerebral Arteries and by Mr. Peyton Beale on the Use of Alcohol as a Wound Dressing deserve attention. Sir W. R. Gowers says that as an indication of previous syphilis great reliance may be placed upon loss of the pupillary action to light, whilst the reaction of accommodation is not impaired. Mr. Beale, whose article we referred to last week, finds that alcohol applied as methylated spirit on double cyanide gauze promotes rapid union of wounds and checks serous exudation, so that the risk of the wound becoming infected after the first dressing is very slight. Dr. Atchley's Note on a Cancer Cure of the Eighteenth Century shows that vaunted specifics for cancer were known more than 100 years before the days of Mattei; and the concluding instalment of Dr. Fletcher Beach's Observations on Mentally Deficient Children is marked by many helpful suggestions on the psychology and treatment of these alien outcasts.

PLYMOUTH INFECTIOUS DISEASES HOSPITAL.—On Sept. 13th the Plymouth Board of Guardians received from their Visiting Committee a report which contained serious allegations as to the treatment of the workhouse children sent to the Borough Infectious Diseases Hospital. On Sept. 16th the hospital sub-committee of the town council held an inquiry into these allegations, with the result that all the charges against the hospital were emphatically denied. The affair had created a considerable amount of interest in the Three Towns and much more will probably be heard about the matter. It is certainly to be regretted that the guardians did not give the Sanitary Committee and hospital officials an opportunity of replying to the charges before they adopted the report.

New Inventions.

A THREE-WAY COCK FOR ADMINISTERING NITROUS OXIDE GAS AND ETHER; FOR USE WITH CLOVER'S INHALERS.

THIS device consists of a T-shaped tube with two telescoping tubes X and Y at either end of the horizontal limb.



A small ether bag is passed over the shoulder B. The gas enters by a tube T and is guided into the bag which it distends. The vertical limb I fits into a Clover or similar inhaler. With both Y and X pulled out the patient breathes air. Push Y in and the inspiratory and expiratory valves are brought into action. Push X in and they are thrown out of action and he breathes backwards and forwards into the bag. The movements are controlled by slot-pins and the letters opposite these indicate the action of the valves, thus for breathing Air the slot-pins will be at A and A G, for breathing Gas they will be at G E and A G, and for breathing Ether they will be at G E and E. The advantages claimed for the apparatus are that it is simple of construction, that it can be fitted to a Clover's inhaler, and that an ordinary small ether bag only is required, and ether anæsthesia can be continued without changing the bag. It has been used by myself and my colleagues at Wolverhampton General Hospital for more than a year with very satisfactory results. It is made by Mr. F. Ash of Birmingham.

J. A. CODD, M.D., B.Sc. Lond.,
Honorary Assistant Physician, General Hospital, Wolverhampton.

IMPROVED ASEPTIC HYPODERMIC SYRINGE AND CASE.

THE accompanying illustration shows a new form of aseptic all-metal hypodermic syringe and case. The advantages claimed for it are, that it can be easily sterilised, that it is durable, that it holds a number of tubes of compressed drugs, all the articles in the case are easily got out, and that, being compact, it can be carried in the waistcoat pocket very conveniently. It is manufactured by Messrs. Reynolds and Branson, of Leeds.

E. MILWYN JENKINS, M.B., C.M. Glasg.
Shaftesbury House, Calverley.

A NEW CATHETER DISH.

THE accompanying illustration shows a dish which I have designed for the reception of flexible catheters in daily use. It consists of an elongated narrow vessel, furnished with an overlapping lid, and it is sufficiently long to admit a catheter of ordinary length without flexion being necessary. The catheter rests on two transverse ridges attached to the bottom of the dish, so that the antiseptic solution with which the dish is filled surrounds the instrument. A flexible catheter, once having been used, has to be bent to be placed in most of the receptacles as used at present and this frequently produces "kinking" or injury at the eye. In my

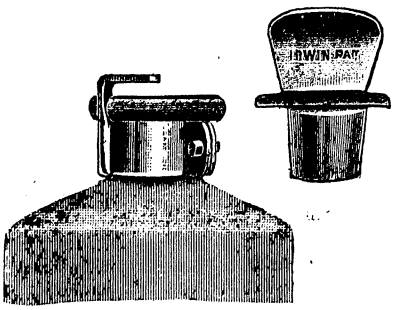
Digitized by Google

dish the catheter can be kept perfectly straight and a minimum amount of solution is required to keep it submerged. The vessel being long and flat it may be kept by a patient's bedside without fear of upsetting it, and the shallow depth combined with the absence of angles renders the dish very easily cleansed and sterilised. A label may be attached

to the handle or the patient's name may be written directly in ink or pencil on the lid. The dishes will serve for all forms of flexible catheters or bougies and may also be used for drainage tubes. They are manufactured of iron, enamel ware, glass, or porcelain, and may be obtained from Messrs. Reynolds and Branson of Leeds at a small cost.

H. DE PAIVA B. VEALE, L.S.A. Lond.,
Late House Surgeon General Infirmary, Leeds.

A MODIFIED UTERINE SOUND.



THE many dangers incidental to the use of the ordinary uterine sound, even in skilful hands, may, I think be avoided by the use of the instrument depicted in the illustration. The various manipulations for which the sound in its original form has been found so useful can be equally effected and without danger by its use in the modified form. During the operations for vaginal or abdominal hysterectomy it will be found useful for lifting the uterus or deflecting it to either side or carrying it to the front or back. The sound is constructed of flexible copper, plated, with the addition of a metal disc on which the os and cervix rest; this is placed two inches from the point, thus making it impossible to penetrate the fundus (the weight of the uterus being borne by the disc and not by the point), which was a serious fault of the original instrument. The entire sound being made of metal can be easily sterilised, while the handle being pear-shaped will afford additional power in manipulation (more especially in operation cases) and be found more comfortable to the hand than the older form. Messrs. Arnold and Sons, London, are the makers.

Cheltenham. ALEXANDER DUKE, F.R.C.P. Irel.

A NEW ANÆSTHETIC BOTTLE.

DR. FREDERIC HEWITT has asked us to draw the attention of our readers to a new and efficient bottle for ether, chloroform, and allied substances. It is the invention of

Mr. Irwin, of 4, Cottage-grove, Stockwell, S.W., from whom bottles of various sizes (6 oz., 12 oz., and 18 oz. capacity) may be obtained. The stoppers are made of a special alloy and each one is ground into the glass neck of its bottle, so that a very accurate fitting results. In placing the stopper in its bottle it has simply to be turned a little and the projecting metal rod shown on the left hand side of the stopper in the illustration wedges more and more tightly under the metal arm carried by the collar round the neck of the bottle. In this simple way perfect accuracy of fitting is secured and the stopper cannot be dislodged until it is released by turning it back. Dr. Hewitt has tried the system for three months and finds that it works well. Each bottle is supplied with a leather case, which has the advantage of being lighter than the wooden case generally used.

FIFTY-SECOND ANNUAL REPORT OF THE COMMISSIONERS IN LUNACY.

THE fifty-second annual report of the Commissioners in Lunacy provides the usual statistical review of the certified insane in England and Wales and a critical retrospect of the different institutions set apart for the care and treatment of those afflicted with mental disease. The total number of persons of unsound mind under the supervision of the Lunacy Commission on Jan. 1st, 1898, was 101,972, being an increase of 2607 over that of the previous year. Figures like these are warranted to arouse a feeling of anxiety in the public mind, and at first sight it would appear that the malady is tightening its grip upon the community. The statistics are no doubt disquieting, but if we accept the views of the Commissioners, set forth in the special report issued last year, as correct, the increase is more apparent than real. The Commissioners attributed the higher numbers to various causes, amongst others the increase in the general population, a gradually diminishing death-rate in the institutions under their control, and an enhanced tendency on the part of relatives and others to send senile cases to the asylums for treatment. These and certain other influences undoubtedly account in a large measure for the increase, but it is more than questionable whether they account for all. It would be well if the Commissioners could see their way to include in their statistical returns a table showing the number of first cases in which the insanity developed itself within three months before admission. There ought to be no difficulty in compiling such a table; it would unquestionably prove a surer means of gauging the actual rate of freshly occurring insanity than some of the theoretical methods so frequently employed. The table itself could not fail to be a valuable addition to the statistical returns presented from year to year, some of which, we regret to say, are absolutely useless and only serve to cumber the pages of the blue-book. The actual increase above notified is caused mainly by a large increment in the pauper class—viz., 2486. There were 124 more private patients and 3 fewer criminal lunatics. The ratio of registered insane to the population on Jan. 1st, 1898, amounted to 32·48 per 10,000, a differential increase of 0·48 on last year's ratio. According to the Commissioners' figures in the year 1859 1 person in 536 was insane, whereas this year it is computed that 1 person in 308 is of unsound mind.

The ratio per cent. of the pauper insane to paupers of all classes is perhaps the fairest test for determining the prevalence of insanity in the community, for the actual pauper population is known and the number of pauper insane within the cognisance of the Lunacy Board embraces, with but few exceptions, the total number of pauper insane in the country. The ratio of paupers to the population is fairly stationary, but there has been a gradually progressive rise in the ratio of pauper lunatics to paupers of all classes during the last decade. The ratio in 1889 was 9·25 per cent.; in 1898 it stands at 11·08 per cent. This represents an actual increase in the ratio of pauper lunatics to paupers of all classes of 1·83 per cent. during the two years, but, according to the official view, as before explained, the increase is mainly due to accumulation and to the gathering within the official net of numbers of the class described as "unregistered lunatics,"

Digitized by Google

whose numbers, notwithstanding annual depletion, seem to be as large as ever.

The total number of patients under detention on Jan. 1st, 1898, amounted to 76,423, an increase on the number on the same date in the previous year of 2843. The total number of admissions during the year, excluding transfers and re-admissions on fresh reception orders, was 19,405, a number 191 in excess of last year's admissions. The actual number of patients discharged as recovered during the year amounted to 7230, being 52 more than in 1896. This increase occurs mainly amongst the private patients. The proportion of "stated" recoveries (the Commissioners carefully emphasise "stated") to the total number of admissions amounts to 38·35 per cent., as against 38·53 per cent. in the previous year. Of the total number of patients under treatment in 1897 7·34 per cent. were discharged *recovered* (the Commissioners' italics).

The death-rate calculated on the average number resident was 9·43 per cent., being 0·38 per cent. higher than in 1896, when, however, it was exceptionally low. The mortality table not only shows the causes of death, but also enumerates the number of post-mortem examinations made and gives the average age at death for each disease. The average age at death for males was fifty years and for females forty-nine years. It is important to note that the average age at death in cases of general paralysis of the insane was forty years, and the average age in cases dying from phthisis was also forty years. General paralysis and phthisis proved the most fatal maladies, the former accounting for 19 per cent. of the deaths and the latter for 14·5 per cent. The proportion of deaths from cerebro-spinal diseases was 40·5 per cent., from thoracic diseases 34·8 per cent., from abdominal diseases 8 per cent., from general diseases 6 per cent., and from other diseases—a group in which senile decay figures prominently—10 per cent.; accident, suicide, and violence accounted for 0·8 per cent. of the death-rate. The inference somewhat hastily drawn in last year's report that insanity in a form requiring treatment away from home is more frequently developed in the spring and summer than in the autumn and winter is not quite borne out on the second appearance of the new table introduced last year, for January occupies quite a prominent position, being third on the list, following closely on May and June.

The severely simple classification of insanity to which the Commissioners tenaciously cling may be described as somewhat out-of-date. In the table giving the yearly average occurrence of the "principal" forms of mental affection for the five years 1892–1896 the classification employed is "mania," "melancholia," "dementia (ordinary and senile)," and "other forms of insanity." It is perfectly certain that such a classification would not be found in any ordinary asylum report and the nomenclature is utterly unsuited to modern ideas.

The yearly average number of epileptics admitted during the quinquennial period 1892–1896 was 7·9 per cent., that of general paralytics 8·2 per cent., and that of patients with suicidal tendency 24·7 per cent.

Intemperance in drink and heredity appear to be the most frequent causes of insanity, but the Commissioners with reason state that "the tables dealing with the assigned causes of insanity are not very reliable."

In dealing with the distribution of pauper lunatics the Commissioners again call attention to the growing tendency to send to asylums cases formerly treated at home or in the workhouse. They state that "this tendency evidently continues to work, for the proportion of pauper lunatics in institutions for lunatics advanced from 74·59 to 75·16 per cent., an increase of 0·57 per cent., while there was a corresponding decrease in the proportions of those treated in workhouses or living with relations or friends. The cases so brought under asylum treatment are those of senile dementia or congenital weakness of mind." This is no doubt the case, but it is worthy of remark that the proportion per cent. of congenital cases to the total of the yearly average number admitted is steadily decreasing, being 4·6 per cent. for the quinquennial period 1892–1896, as against 5·7 per cent. forthe quinquennial period 1888–1892.

Owing to the opening of four new establishments the number of county and borough asylums is augmented to 74, the patients in these institutions being classified thus: private, 1254; pauper, 67,759; criminal, 120. The number of fresh admissions was 283 in excess of that of 1896, and it exceeded the average of the ten preceding years by 2317. Of these fresh admissions no less than 16·1 per cent. were cases readmitted into asylums from which they had previously been discharged. It is a significant feature that the proportion of such readmissions is steadily rising year by year, and it comes to be a question of serious import whether, owing to the number of admissions and the great lack of accommodation, there is not a tendency on the part of asylum authorities to create vacancies by shortening the course of treatment, and allowing the discharge of patients who have apparently recovered, but whose mental equilibrium has not sufficiently regained that balance, which is required to withstand the worry, the excitement, and the temptations of every-day life. It would really seem that the Commissioners are justified in using the word "stated" when alluding to recoveries in their statistical tables.

The deaths in the county and borough asylums amounted to 6659. Post-mortem examinations were made in 79·3 per cent. of the cases, a proportion almost identical with that of last year; the percentage of such examinations varies greatly in the different asylums. The deaths from suicides numbered 11; in two instances, however, the act was committed when the patients were absent on leave, and in another prior to admission. This is exactly half the number recorded in the previous year, and affords satisfactory evidence of the vigilance and care exercised by the staffs of the various asylums. Two murderous attempts were made by patients during the year; in one case upon a superintendent and in the other upon a male attendant. Fortunately neither was followed by a fatal result, but the repeated occurrence of such incidents clearly shows the dangers of the service and accentuates the claims of those engaged in it to exceptional liberality of treatment. This aspect of asylum life ought certainly to be borne in mind by the Legislature when the pension clauses of the belated Lunacy Bill again come up for discussion in the ensuing session of Parliament. 21 asylums are scheduled in which insanitary conditions prevailed to a greater or less extent. Typhoid fever, erysipelas, and colitis bulk largely in this return. Overcrowding, with all its attendant evils, is no doubt largely responsible for this state of affairs. The Commissioners have found it desirable to give particulars of various matters of detail affecting individual asylums. These relate principally to building extensions, insanitary conditions, overcrowding, fatalities, and suicides. While expressing regret at the burden imposed on the ratepayers they urge the need which exists for further accommodation for pauper lunatics, and state their conviction that delay in this respect is essentially false economy. The question whether the visiting committee of a county and borough asylum is entitled to charge a larger weekly sum than 14*s.* for out-county patients was referred to the Commissioners. They submitted a case for the consideration of the law officers of the Crown, who replied that in their opinion such larger charge could legally be made. Prohibitive rates will be a powerful factor in inducing those districts which have not the necessary accommodation to adopt measures for housing their pauper insane. The number of registered hospitals remains at 14. There are 7 institutions for idiots and 70 licensed houses. With regard to the latter the Commissioners express their approval of the efforts made to improve the accommodation for patients and to add to their comfort. They have to report, however, an unusual number of suicides in these institutions. Some correspondence took place between the Foreign Office and the Commissioners relative to the alleged detention of a number of British subjects in a French lunatic asylum. The matter was referred to the law officers of the Crown but no action was taken, the Commissioners being of opinion that no useful purpose would be served by taking proceedings. They express themselves as being well satisfied with the state in which they found the various institutions under their supervision.

All those engaged in lunacy work will echo the expression of regret made by the Commissioners concerning the sudden death of their valued colleague Dr. Wallis. His place on the Commission has been taken by Dr. Marriott Cooke, for many years the medical superintendent of the County and City of Worcester Asylum. Lord Hatherton has resigned his chairmanship of, and seat at, the Board.

On the whole the report maintains its high standard as an official record of the careful supervision exercised over the certified insane under increasing difficulties, and notwithstanding a few defects, to which attention has been drawn, it should prove an interesting study to all who are entrusted with the care and treatment of the insane.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 24, 1898.

THERE is still much obscurity about the pathology of the curious spasmodic affection known as "tetany," of which the main characteristic is an intermittent tonic contraction of the muscles of the extremities, especially of the fingers and toes, although the spasm is not in all cases so limited. It does, however, differ from true tetanus in its mode of onset, as well as in the march of the spasm, and also—except in the grave forms with which we propose immediately to deal—in its comparative benignity. It was not until the appearance of TROUSSEAU'S classical lecture on the subject that much attention was paid to the affection, although, as TROUSSEAU himself points out, it had even then been known and described several years before. He himself had been struck by the frequency of its occurrence in nursing women and in those who were recently delivered, so that from his early experiences he had gone so far as to term it "rheumatic contraction of nurses," the conception of a "rheumatic" basis being favoured, according to the knowledge of the day, by its apparent relationship to chill. He came, however, to recognise that this was but a partial description, although he never realised the full extent of its associations. However, in course of time he met with cases in both sexes and at various ages, many in infancy, when perhaps it prevails the most. He also found that it was frequently associated with teething, with chronic diarrhœal disorder, and that it might follow upon cholera and typhoid fever. At the same time he thought that its most common direct antecedent—its "exciting cause"—was exposure to cold. Readers of his lecture need not be reminded of the accuracy of the clinical picture which TROUSSEAU delineated. Little has been added by those who have come after him, whilst to him is owing the observation that the spasms can be excited by compression of the main nerve-trunks and blood-vessels. By him tetany was regarded as a comparatively trivial affection, for although he was careful to distinguish between the mild, moderate, and severe types—a distinction founded mainly upon the less or greater amount of general disturbance—he said that he had only met with one case in which death could be directly referred to the tetaniform condition. For the most part in his experience the symptoms would pass away within a variable period, the spasms intermitting with lessened frequency until after the lapse of a few weeks or a month recovery was assured.

Since TROUSSEAU wrote, many have contributed to the subject, especially writers upon diseases of children in whom it has been found to be largely associated with rickets and with the diarrhœa or general marasmus which may accompany that nutritional disorder. Yet there still prevailed a very hopeful view as to the prognosis of cases of tetany. It was not until attention came to be directed to the supervention of tetany upon gastric dilatation in adults that a change took place in this favourable prognostic opinion. In association with that visceral condition tetany assumes a more serious significance and its supervention must always be regarded with anxiety, if not with alarm. Hence writers upon diseases of the stomach speak in quite different fashion from TROUSSEAU and others as to the outlook in cases of tetany; they aver that its prognosis is "very bad" and mention 70 per cent. as the mortality of cases in which it arises. This changed attitude in regard to the character of the affection is borne out in the papers by Dr. SOUTTAR MCKENDRICK and Dr. TREVELYAN, which we publish elsewhere, and which, moreover, contain all that can be said on the subject, the interest of which does not rest merely upon its comparative rarity. Indeed, we are sanguine that the appearance of these suggestive and full records may lead to further contributions and perhaps to the demonstration that tetany and allied states in less grave forms are observed in association with gastro-intestinal diseases more frequently than is generally believed.

The clinical features of a well-marked case are readily recognised, but the questions which afford most scope for discussion are those connected with its etiology and pathology. These have been fully and ably discussed by Dr. TREVELYAN, so that we ought almost to apologise for venturing to make any further comments on the subject were it not that some good may be done by exciting interest in this "gastric tetany," as he succinctly terms it, by fixing attention on the problems which surround it. Now, although tetany may be met with in association with many and varied states its relationship with dilatation of the stomach appears to be so definite and, so to speak, so constant (using the term in a general sense) that it must, in such cases, depend on the conditions peculiar to that state of the viscus. The main circumstance is of course the retention of more or less partially digested material in various stages and kinds of fermentation. It is conceivable that these may act as irritants of gastric nerves and thus excite reflexly the muscular spasms of the tetanoid state. The fact that tetany has been known to supervene on lavage of the stomach, or even during its performance, might be cited in support of such a view, and perhaps the remarkable frequency of tetany after thyroidectomy might be deemed also to bear on the theory of nerve irritation. But nowadays, and not without reason, the doctrine of reflex nerve irritation has been found insufficient in cases where it was formerly thought to explain all. The "reflex neuroses" are fast becoming obsolete, and wherever a more tangible theory can be framed it is to be preferred. Another view, propounded by KÜSSMAUL and supported by some, is that the whole nervous system shares with the tissues generally in a dehydration owing to the excessive loss of water by copious vomiting, as well as by the abundant secretion which is poured into a dilated stomach. To our thinking more satisfactory and more rational is the reference of the condition to toxic agencies, and this on more than one ground. In the first place, the production of toxins of many and varied properties cannot but occur in the fermenting contents of a dilated stomach. In the second place the experiments of BOUCHARD

Digitized by Google

have shown that some of the products of urinary excretion in health and disease are direct poisons to the nervous system. What, then, is more likely than that in certain subjects, and under certain conditions which cannot as yet be formulated, poisons are produced which are capable of exciting the nerve centres so as to produce the phenomena of tetany? It should, of course, be possible, if this were the case, to analyse the contents of a stomach after the method adopted by BOUCHARD in respect to the urine, so as to ascertain whether they included any nerve poison of this type. Perhaps this may be done in the future. Meanwhile we must be content to act on the hypothesis and must not hesitate in cases of gastrectasia in which this dreaded complication is arising to thoroughly relieve the stomach of its contents. In one of Dr. TREVELYAN'S cases some temporary relief was obtained by this measure, but the patient sank from exhaustion. It is noteworthy, however, that on the previous day when the symptoms were fully marked, there had been a fruitless attempt at lavage, and it may be that the performance of the operation is too difficult in such circumstances. This is all the more reason why attention should be drawn to the earliest symptoms, in order if possible to resort to lavage before the tetany becomes fully developed. Nor can we pass from the contemplation of these fatalities without raising the question again as to the probability of the occurrence of slighter manifestations of nervous disorder directly referable to the gastrectasic condition. *A priori*, if the toxic theory be the correct explana tion, it might be thought, considering the large number of cases of gastric dilatation and the fewness of the severe and fatal cases of tetany which complicate them, that cases of less severe intoxication should not seldom occur. Cases of slight and transient spasm, of cramps, of temporarily deranged sensation may arise and be so trivial as to escape the observation of the medical adviser or be disregarded by the patient himself. So, if they do occur their existence would go far to confirm the opinion of the toxic origin of tetany, which is not gainsaid by the conditions of its occurrence in children, in nursing women, or after thyroidectomy.

THERE are two Italies, and they are as wide as the poles asunder. There is the Italy of romantic tradition and there is the Italy of prosaic reality. It is as the former that outlying Europe, or we should rather say the English-speaking world, persists in regarding her, and with consequences by no means favourable to Italy herself. The interest she has inspired and the sympathy she has aroused have made her the "spoiled child" of her more civilised contemporaries, bringing her moral and material help which had far better have been evolved from within her own borders, to the reinvigoration of her own character and to the acquisition of self-reliance, independence, and the nobler virtues which spring from such discipline. Her liberty and her unity she owes mainly to external forces—to foreign allies who, like France and Prussia, assisted her for ends not wholly unselfish, or who, like Great Britain, gave her a moral, and in the long run a more substantial, because disinterested, support. After she became united and free it was still to the kindly outsider that she was indebted for material as for moral aid. To the English-speaking visitor she owes about one-third of her revenue in gold; to the English-speaking world she almost spontaneously looks for sympathy and succour in political adversity or calamitous visitation. Does a disastrous flood reduce one of her districts to homelessness and want, Great Britain's charitable aid is always forthcoming. Does an earthquake bring ruin on one or other of her islands, the same free-handed largess is never appealed to in vain. So much is this the case that such visitations are looked upon by provincial Italians as "providential" in a double sense—"Providential" as coming from on high; "providential" as providing means often much in excess of the occasion which evoked them.

Italy, indeed, has, by the rueful admission of the best of her publicists, come to be a "moral mendicant," with the disastrous consequences to character induced by such a *rôle*. Beggary is an "institution" within her borders, and those of her sons who try to put it down by introducing the atmosphere of self-respect which should be fatal to it find in the thoughtlessly free-handed Englishman or American the greatest obstacle they have to encounter. This indulgent attitude towards her and hers has all the force of a conspiracy—kindly, if unconscious—to keep her *in statu pupillari* among the nations—to perpetuate the truth of MASSIMO D'AZEGLIO'S bitter exclamation: "Fanciulli siámo" (children we are). Her well-meaning but injudicious friends are, indeed, her worst enemies, who have only to be a little more familiar with her or her real, not her romantic, side to do her the genuine and lasting service of leaving her to work out her own salvation.

"Italia farà da se" (Italy will suffice for herself) was the watchword of the creators of her "Risorgimento," and it is high time that she revived it and made it practically operative. She has within her own personality all the means of self-rehabilitation, but she must be taught to rely upon them. "The cleverest people in Europe if only they had staying-power," was the verdict of a great British engineer who had been in touch with their inner life for nearly half a century. "Steadiness, steadiness, the English steadiness," was the one requisite they needed for success in GARIBALDI'S estimation. But how to acquire it when the moral fibre, relaxed by long subjection, is kept flaccid by influences from without and never feels the tonic of effort from within? The native genius is in these circumstances perverted and all its development moulded to the utilisation of opportunity casually presented, not to the creation of means or the fusing and welding of nature's own material for the working out of ends conducive to common good. We have thus in Italy a mediæval spirit struggling for existence amid nineteenth-century institutions, showing admirable ingenuity and subtlety and nimble resource as a substitute for the manlier, maturer, and more effective qualities of latter-day evolution.

Corruptio optimi pessima est. There is more wit and talent put forth in Italy for the attainment of illicit objects than healthily constituted countries expend on legitimate undertakings. We have to go back to "Gil Blas" for examples of clever knavery similar to those perpetrated in the kingdom every day. Even crime

Digitized by Google

within its borders is romantic and serves to keep up the fatal "interest" in Italians which makes them the object of a foolish fondness on the part of other peoples. Leaving aside the brigandage which, as in the recent case of the Tuscan Tiburzi, recalls the "forest days" of ROBIN HOOD, we find the swindler plying his *métier* with a dramatic skill which extorts an unwilling admiration. Take two specimens which came off within twenty-four hours in the city of Florence not so long ago. The scene is a *trattoria* or restaurant in the suburbs. A young man and his sweetheart are at a table conversing over a frugal meal. Presently a well-dressed gentleman comes in and at another table orders a more luxurious repast. The landlord is attracted to the first-mentioned table—the pair being obviously in difficulties. The young man has forgotten his purse. "I cannot let you go without paying," says the irate Boniface; "you have a watch, leave that with me and then you may go home for the purse you say you have left behind." The young man, not without protest, gives up his chronometer and the landlord is returning to his coign of vantage, when the gentleman, who has been a witness of the scene, rises and stops him. "Your conduct to that young man, sir," he says, "is shameful. Anyone may forget his purse. Give him back his watch and include his bill in mine and let him go if you ever want me as a customer again." Producing a pocket-book well filled with bank-notes the gentleman hands a 100-franc *bigliétto* to the landlord, who sulkily restores to the youth his watch, makes up the double bill, and gives the gentleman some 90 francs in change. First the pair go out and then the gentleman, leaving the landlord half glad and half sorry for the incident which gave him his money and cost him a reprimand. Days afterwards he has to pay a large sum, towards which he adds the 100-franc note received from the gentleman, only to find it a clever counterfeit. While this drama *à la* LE SAGE was being played another even more effective was in course of performance. At an hotel, also in Florence, a traveller for a large jewellery firm has put up and is already doing good business. A gentleman appears, makes purchases to the amount of twelve hundred francs, for which he gives notes of unexceptional genuineness and goes his way. An hour afterwards a delegate of *Pubblica Sicurezza* comes in and takes the traveller aside, wishing to have a word with him privately. "You have just sold some jewellery," he says, "to an individual who paid you twelve hundred francs for it?" "I have," replies the traveller. "You have been victimised, sir, by a swindler well known to the police," says the *delegato*. "How so?" inquires the dismayed traveller. "There are the notes. They are perfectly genuine." "They are nothing of the kind," says the *delegato*. "They are imitated admirably—the work of a well-known gang of forgers. But keep your mind at ease. Your jewellery is quite safe at the police-office, where you will find it along with the swindler, whom we have arrested. Call there at four o'clock and you will get your property back. Meanwhile give me the notes. They are required to identify the forgery." The traveller gave up the notes, called at the police-office, found neither delegate nor prisoner, but found only that by consummate acting he had lost twelve hundred francs' worth of jewellery and also the perfectly good money which had been paid for it.

Such occurrences are of daily experience and explain the phenomenon that Italian fiction is poor—poor out of al proportion to the literary skill of the people. It is beaten out of the field by fact, chronicled day after day by the police-reporter. When is all this perversion of ingenuity and labour and forethought to be replaced by the honest employment of the same qualities towards legitimate ends? When Italy becomes true to herself, is the answer; when she recognises the fact that, "hooked on to the express train of the nineteenth century," she must conform to the new conditions of progress; and, above all, that she must count as her worst enemies those whose kindly forbearance with her shortcomings and free-handed ministration to wants of her own contracting keep her in the mediæval stage from which she was supposed to have emerged.

LORD WOLSELEY'S homily on Intemperance and Immorality among Soldiers, which was issued as an Army Memorandum last April, has now been republished in the form of a Parliamentary paper and will, no doubt, thereby gain in weight. His lordship in forcible language calls upon all officers in command of troops, batteries, and companies to perform their bounden duty in directing and controlling the morals of the men over whom they are placed in authority, and that not only by precept but also by example. Young soldiers in particular should be encouraged to look to their superiors for example and guidance amid the temptations which surround them and to expect ready sympathy and counsel in all their difficulties and troubles. Officers and also non-commissioned officers are repeatedly directed to do their utmost to promote a cleanly and moral tone among the rank and file and to spare no effort in watching over the physical and moral welfare of the men for whose proficiency in military exercises they are responsible. This is certainly expecting a great deal, for it must be remembered that the vast majority of company officers are young men themselves, obnoxious to the same temptations as the private soldier and totally destitute of special training as instructors in morality. British officers, however, have invariably proved themselves worthy of trust and the nation may with confidence expect to see the Commander-in-Chief's instructions fulfilled in the spirit as well as in the letter. Throughout his Memorandum Lord WOLSELEY deals in generalities—with one single exception. "Surprise visits" for the detection of suspected immorality are enjoined and this, we venture to say, is a weak point in the otherwise admirable exhortation. Everything which savours even distantly of espionage should be avoided in the management of British soldiers. The British soldier is *primâ facie* an honest man and must on no account be treated as though he were *ipso facto* an evil-doer. If he finds that he is liable to be tracked and pounced upon as though he were a hardened criminal he will very soon lose his self-respect and seek in every underhand way he can think of to outwit the detectives set over him. Straightforwardness is the best policy in dealing with the class of man whom it is desirable to attract as a recruit. Trust your soldier and let him see that you do so, should be the golden rule amongst all who

Digitized by Google

are charged with authority in the army. On active service spying out the enemy is no doubt advantageous, but as an item of internal economy among grown men in barracks surreptitiousness of every description should be rigorously interdicted. With regard to the preliminary training of both officers and private soldiers there are several points which urgently demand attention. Before a recruit is allowed to fire ball-cartridge he must have given proof that he thoroughly comprehends the mechanism of his piece as well as the effects of the discharge. Should his arm be the lance or the sabre his dexterity with these weapons is tested before he is allowed to manipulate them at large. Drills without number and exercises beyond computation have to be endured before the neophyte receives permission to take his place in the ranks. In a word, the utmost care is taken to educate the young soldier in the art of killing or maiming his enemy, but by stopping short at this point the instructors have only half equipped their man. In order that a soldier may be in a condition to do his country the maximum amount of service it is necessary that the art and science of taking care of his own health should be included in his curriculum. Even on home service it is highly desirable that this should be so; but abroad, where our troops have to live under conditions largely differing from those to which they have been accustomed, it should be made a *sine quâ non*. When a soldier fails to preserve his health he forthwith becomes an encumbrance in the field, a source of weakness instead of a source of strength. Not only are his individual services wasted, but also the services in whole or in part of several of his comrades. As regards the efficiency of the force it would be better for him to die than to fall lame. For a soldier actively engaged there is nothing more important than health and yet no attempt is made to teach him how to preserve it. In addition to teaching their men how to be moral it would be well if commanding officers were to be directed to teach them the essentials of personal hygiene, with especial reference to the requirements of the locality where they might happen to be serving. A course of lectures at the canteen could not but be advantageous provided the lecturer were properly equipped for his task. Of this, however, he would need to furnish unquestionable proof, for of all branches of knowledge in which a little learning is a dangerous thing there is none to surpass self-medication.

THE recent regulations of the General Medical Council prohibiting the employment of unqualified assistants, save in an entirely subordinate way, have a very obvious application in holiday times. It is absurd to think that although an unqualified assistant may not be allowed to have sole or serious charge of cases, yet such an assistant may be left in a position by his principal during the holidays which would place him at any moment in responsible care of the whole practice. This very obvious point seems to be overlooked by some practitioners. During the holiday season in past years medical men have experienced the reality of the risk and have been subjected to the odium and the inconvenience of censure at inquests as well as of being brought before the General Medical Council with the chance of being found guilty of infamous conduct in a professional respect, and of having their names erased from the Register. There is too much reason to think that the warning conveyed by these facts seems to have been, like so many other warnings in the matter of unqualified assistants, overlooked. In one case recently investigated by Dr. WYNN WESTCOTT and a jury an unqualified assistant, in the absence of the principal, was sent to a serious case by the qualified assistant. The excuse of the qualified assistant was that he could not be in two places at once, and that "half a loaf" (an apt name for an unqualified assistant) was better than no bread. In the end the qualified assistant was censured and the coroner was asked by the jury to forward a report of the proceedings to the principal "and to the General Medical Council so that they could take what steps they thought necessary in the matter." It is not for us, of course, under these circumstances, to pass any judgment on the facts of this particular case. But we should fail in our duty if we did not give them prominent notice as a lesson to others. A holiday should be no holiday to a medical man if made under conditions of such risk as we have described, for his apprehensions of mischief should prevent him from enjoying himself. The instructions and arrangements of a principal on leaving town should be such as to make sure that his patients can be attended by a qualified representative. It is only by such arrangements that he can enjoy that sense of irresponsibility which, after all, is the very essence of a holiday. It may be said that the remuneration of medical practice in poorer neighbourhoods will not always admit of a principal keeping qualified assistants or paying qualified locum tenents. Then the public must understand that if they are to have fully equipped medical men they must pay for the service they receive. But we can scarcely think it possible that in any part of London a medical man would not be able to make arrangements with his medical neighbours so that they might share his responsibilities in his absence. The cultivation of neighbourly amenities is not only a duty but an advantage, and one at no time more obvious than in holiday seasons.

Annotations.

"Ne quid nimis."

COUNTRY HOUSE DRAINAGE.

THE problem for solution in a letter signed "South Dublin" which will be found on p. 846, is one of perplexity to most responsible dwellers in rural districts. The extremely unsatisfactory provision for the disposal of the house drainage described in our correspondent's letter is shared by many thousands throughout the country. The great importance of the question induced us recently to issue a Commission upon the subject of water-supply and the disposal of sewage in rural districts, the two questions being so intimately connected. The result of this inquiry will shortly be published and will afford more complete information than can be given in an annotation. Soak-away cesspools, such as are described by "South Dublin" are not only objectionable but must constitute a source of grave danger to the springs from which the water-supply is derived. The sewage, escaping as it does under pressure below the surface of the ground, depends entirely upon mechanical filtration through the soil

Digitized by Google

for its purification, and in a limestone district will often travel for miles through fissures without undergoing any material improvement. Bacterial life, the mainstay upon which we depend for the breaking up of organic into harmless inorganic substances, scarcely exists 12 in. below the surface of the ground, and can therefore exercise no influence upon matter escaping below this point. The contamination of the rain-water by first discharging it into the cesspool and afterwards having to disinfect it seems a somewhat useless mode of procedure. This should be made to go directly into the ditch mentioned by our correspondent. Disinfectants are at best but a poor substitute for the process of disintegration provided by nature through the means of bacteria, the existence of which process recent research has revealed. Experiments have proved that secondary decomposition invariably takes place in a short time after using disinfectants; they do not prevent but only delay a natural process. If used, quicklime is perhaps the best and cheapest for this purpose, and in this case it should be thrown into the ditch. The principle which would appear to provide at once the simplest and the most effective method of dealing with domestic sewage where water carriage is adopted, is one which was first practised by Mr. J. Scott Moncrieff in his microbe cultivating tank. This consists of passing raw sewage through a brick channel filled with round stones upon the surface of which various bacteria of a non-pathogenic character always present in excreta rapidly multiply. They convert the solid organic constituents into a liquid form. This view is confirmed by the experiments carried out a short time back by Mr. Dibdin (when chemist to the London County Council). This gentleman passed large quantities of raw sewage slowly through a pit filled with various materials, such as coke, burnt ballast, small stones, &c. He found that a comparatively clear effluent was obtainable with either material, provided that the pit or filter had at least one week's rest in five. He found the coke perhaps the least desirable. For such a case as that described by "South Dublin," in place of the existing cesspool two channels or filters would be required, formed side by side. They should be six or eight feet long by three feet wide and cemented internally to prevent the escape of the liquid sewage. These should be filled to a depth of about two feet with stone or pieces of burnt ballast measuring, say, about two inches over each piece. The effluent should be made to flow out at the level of the top of the stones, and provision must be made for running off the liquid from each filter once every month, the incoming stream being diverted into the neighbouring filter, for which purpose some simple provision must be made. The effluent can then be allowed to pass into the ditch without any annoyance being caused. It is better to fill the filters above the stones to the level of the ground with washed gravel. At periods varying from six to twelve months the stones must be taken out and laid at the side of the filter so as to be exposed to the air, but they must not be washed, and any accumulated sludge should be removed from the bottom of the filter. This last had better be buried at once in the ground. Mr. Scott Moncrieff's tank provides the most satisfactory conditions for the conduct of the foregoing arrangement, but how far the application of the principle is covered by his patent rights is a detail.

THE HURRICANE IN THE WEST INDIES.

THE recent hurricane in the West Indies, which affected principally the group known as the Lesser Antilles, has worked great havoc. The islands which have suffered most are Barbadoes, Santa Lucia, and St. Vincent. The governor of Barbadoes has telegraphed home that 50,000 persons are homeless, and he most earnestly entreats financial help as in its present financial condition the colony is quite unable to bear the strain. Up to Sept. 19th 83 deaths had been reported. The Administrator of St. Vincent sends the following report: "Speaking generally, about three-quarters of the population, 41,000, are shelterless, without food, and crowding into the populous centres, which have no accommodation for their own inhabitants, much less for the hundreds of others who are coming in. From Argyle to Kingstown on the windward side there is not a single works or estate house standing. From Buccament to Kingstown on the leeward side everything is destroyed. Kingstown has hardly a house uninjured, and most of them are in ruins; two vessels are ashore, two have sunk, and the fate of others is unknown. It is unnecessary after this to say that almost all the labourers' houses are lying flat. There are at least fifty deaths that are known of the people that are flocking into Kingstown from all the country round for shelter and food, which I am endeavouring to supply for the moment until the weather clears and we can take the damage in detail. So far I have no news of the country beyond Argyle to windward or beyond Buccament to leeward, but I fear that the disaster there cannot have been less than in the southern part of the island. Reports from windward report everything as far as Grand Sable a wreck; that there are two large ships and one small one ashore on the windward coast, and the manager of Sans Souci, Mr. Hillocks, has been killed. From leeward everything is a wreck with much loss of life; in Barrouallie everything levelled to the ground except three buildings; Château Belair reported not to have suffered so heavily, but no reliable information yet." The Governor is borrowing necessary funds to provide relief. From Santa Lucia the accounts are as follows: "Tremendous rain with thunder and incessant lightning all Sunday (Sept. 11th) night. The following information received to-day from coast: 'Immense landslips at Soufrière; five deaths; ten houses and two bridges washed away. A tidal wave did much damage at Choiseul; 7 deaths occurred from landslips. Cocoa estates have suffered immense damage and many are quite ruined. No news from westward; roads impassable; all telephone lines down. Steamer *Deramore* returned to the port last evening with three men rescued off this island from waterlogged schooner *Ocean King* of Saint Vincent.'" Food is running very short in St. Vincent and a steamer has been sent from Trinidad with supplies.

SHOULD PREGNANT WOMEN WORK?

IN a paper in the *Annales de Gynécologie* for August, 1898, Professor Pinard continues his observations with regard to the influence of rest on the part of the mother during pregnancy upon the development of the fœtus. In a previous paper he had shown by observations upon 1000 infants, 500 born of mothers who had had to work up to the end of their pregnancy and 500 born of mothers who had been able to rest for varying periods not longer than ten days before their confinement, that there was a marked difference in weight in favour of the children of the latter class. In further confirmation of his views he quotes from a table drawn up by Dr. Bochimont, based upon 4445 cases showing the average weight of the children of women who had been compelled to work during the whole of their pregnancy and of those who had been able to rest for periods of two, three, or more months. From the results set out in the table he comes to the conclusion that the average weight of the child of a woman who is able to rest for the last two or three months of her pregnancy is greater by at least 300 grammes than that of the child whose mother is compelled to work up to the date of her confinement. The explanation of this difference appears

Digitized by Google

to be the fact that the duration of pregnancy in the former class is more frequently normal, while in the latter it is often prematurely interrupted. The more frequent occurrence of premature confinements amongst the workers he attributes to a tendency to premature expulsion of the ovum produced by a greater descent of the uterus into the pelvis. The truth of this assertion is to some extent confirmed by the observations of Dr. La Torre upon the development of the fœtus in women with contracted pelves. Dr. La Torre's conclusions are that premature confinements are more common in women with normal pelves than in women with contracted pelves and that the products of conception attain the same degree of development in the former as in the latter class. Professor Pinard from his experience goes further than this and holds that the average weight of the children of women with contracted pelves is greater than the average weight of the children of women with normal pelves. The condition of a woman with a contracted pelvis he regards as comparable to that of a woman who is able to rest during the last few months of her pregnancy, in that the child is lying mainly in the abdominal cavity and to a less extent than usual in the true pelvis. In the case of a woman, on the other hand, who has to work standing or sitting the tendency is for the child to lie low in the pelvis and as a result of this premature delivery not uncommonly occurs. Many factors no doubt enter into the question of the development of the child, and it is asserted by some writers that the physique of the mother herself must largely determine the size of her child. The fœtus *in utero*, however, has been well termed a true parasite, and, as Professor Pinard points out, cases of contracted pelves in which the mother is often mal-developed and of small stature seem to show that the development of the mother has but little influence, since in these cases the children show no corresponding want of development, but on the contrary are often above the average size. In conclusion, he cordially agrees with Dr. Bochimont's recommendation that "from the point of view of humanity, from the point of view of the increase of the population, from the point of view of the evolution of the French race it is necessary that the public authorities should intervene to safeguard the pregnant woman during the last three months of her pregnancy and the fœtus during the last three months of its intra-uterine life." Such paternal intervention is hardly likely to be ever necessary or called for in this country, but from a consideration of this paper the interesting question arises, What is the best mode of life for a woman to pursue during the last three months of her pregnancy? Should she be allowed to work or to take exercise, or is she best kept at rest as much as possible? A compromise must no doubt be effected between these two extremes, and while the interests of the mother will be best served by a moderate amount of exercise and a minimum amount of work the development of the child and the avoidance of a premature confinement would appear to be most favoured by a maximum amount of rest.

A CENTRAL BACTERIOLOGICAL LABORATORY FOR LONDON.

A CORRESPONDENT writes: A short time ago the London County Council addressed a communication to each of the vestries and district boards throughout the metropolis asking them whether they would be in favour of the Council applying for Parliamentary powers to establish a bacteriological laboratory. The idea is to appoint an expert or experts in connexion with the projected institution, or otherwise to make arrangements whereby medical officers of health and medical practitioners in London can obtain at the expense of the county the examination by a competent bacteriologist of material from suspected cases of infectious disease, with a view to aiding in the diagnosis. Owing to the summer vacation of the various local authorities the proposition has not yet been fully considered by the majority, but as far as those are concerned who have paid attention to the question the scheme has met with unanimous approval. Among those authorities who have already pronounced in favour of the project may be mentioned Bermondsey, Shoreditch and St. Pancras. In the case of Shoreditch the Health Committee of the vestry point to the laboratory established by the City of New York some five years ago in connexion with a scheme for general bacteriological examination of cases of diphtheria and state that it has been received by the medical profession of that city with almost unanimous approval. The Shoreditch committee mention further that several towns in the provinces and some of the London sanitary authorities appear to have also made arrangements whereby medical practitioners can send pathological material to experts for bacteriological examination. Believing that it would be desirable in order to secure uniformity and economy that such provision should be made, the Shoreditch vestry has just informed the London County Council of its advocacy of such a laboratory. In St. Pancras the vestry has already made some progress in the direction indicated, since from a report just submitted to the Health Committee by Dr. John F. J. Sykes, medical officer of health, it appears that the vestry early last year sanctioned the examination of pathological material in doubtful cases of diphtheria and typhoid fever, the examinations being made when necessary and when considered essential to the proper notification and prevention of the spread of the disease to which they apply. Two questions have to be considered: (1) whether it is more desirable to carry on the work locally or to centralise it, and (2) if centralised, which is the best method of centralisation. In this connexion the Health Committee of the St. Pancras Vestry states that the systems have been organised by the several sanitary authorities in conjunction either with the British Institute of Preventive Medicine, the Clinical Research Association, or the bacteriologists of the large London hospitals. At the same time the small hospital laboratory at each of the larger infectious diseases hospitals of the Metropolitan Asylums Board is utilised for the purpose of examinations of this nature. Taking all the points into consideration, the St. Pancras vestry has come to the conclusion that a central bacteriological laboratory should be established and has expressed the opinion that such an institution could be provided by the Metropolitan Asylums Board, under the latter's Parliamentary powers, in the new premises now being built on the Victoria Embankment. A letter to this effect has recently been addressed to the London County Council. As the London County Council does not meet until next month and as the vestries and district boards are only now beginning to resume their proceedings, some little time will elapse before all the replies are in the possession of the Council. As these will not require much consideration, it is possible that the Public Health Committee may be in a position to submit to the Council a recommendation on the subject early in November next.

POISONOUS SHRIMP PASTE.

THE indiscriminate way in which the sea water bordering our coasts is sometimes polluted is sufficient in many instances to account for the symptoms of poisoning now and again occurring after the consumption of fish. In the case of shell-fish which are eaten without being cooked the symptom may be very possibly due to the action of micro-organisms. In the case, however, of poisoning by cooked fish no such explanation is admissible. It is difficult, therefore, to account for the number of cases of acute poisoning which occurred at St. Anne's-on-Sea, near Blackpool, a week or so ago. Shrimps in this case were the *fons*

Digitized by Google

et origo mali. The shrimps were potted and had been cleaned and cooked in the usual manner and converted into a paste with the aid of butter. The symptoms were precisely those of irritant poisoning—diarrhœa, vomiting, and severe pain, especially in the bowels, being very marked. Some forty people were thus affected, but happily medical advice was soon sought and no fatal result was recorded. It would be interesting to know whether an analysis of the shrimp paste was made and if so whether it threw any light upon the occurrence. Possibly the shrimps may have assimilated a mineral poison, notable quantities of copper, for example, having been found in certain shell-fish. It would seem more probable, however, that the poison was organic in nature—some obscure product of decomposition consequent upon the prevalent excessive heat. In THE LANCET of Sept. 10th we pointed out the great number of cases of poisoning which occurred within a few days and which were due to some mysterious changes taking place in composition through prolonged exposure to a temperature approaching blood-heat, the most favourable point for the fostering and growth of micro-organisms and consequently their poisonous excreta. In the absence of further evidence it is probable that the shrimp paste, especially as it was fairly fresh, had undergone similar changes.

THE APPLICATION OF STEAM TO THE INTERIOR OF THE UTERUS.

DURING the four years which have elapsed since Snegirjeff first proposed the use of superheated steam for the arrest of hæmorrhage a good deal has been written upon the employment of this agent in the treatment of bleeding from the interior of the uterus. Amongst others, Pincus of Dantzig has used this mode of treatment with very encouraging results. He has perfected two methods of carrying it out which he terms respectively atmocausis and zestocausis. In the first the steam is applied directly to the interior of the uterus by means of a double-channelled intra-uterine catheter (atmocautery) provided with fenestræ in both tubes; in the second the steam is employed to heat the outer tube, which is unfenestrated and which then acts as a cautery (zestocautery), and can be applied to any part of the uterus which it may be desired to treat. The intra-uterine application of steam is not without its dangers, and the fact that the result aimed at in certain cases is total obliteration of the uterine cavity shows what it is capable of effecting and at the same time what disastrous results may follow if it be not carefully used. Two cases of unintentional obliteration of the uterus have been recorded, one by Baruch where the method was employed to arrest secondary post-partum hæmorrhage, and the other by Otto von Weiss where in a young girl, aged nineteen years, steam at 100° C. was applied for three-quarters of a minute to the interior of the uterus for the arrest of profuse menorrhagia. The duration of the action should be from ten to thirty seconds. If total obliteration of the cavity be desired it must be continued for from two to three minutes. The steam generated in a vessel furnished with a safety valve is used at from 100° C. to 115° C. Preliminary dilatation of the cervix is necessary in all cases, and if the action is to be limited to the interior of the body of the uterus gauze must be bound round that portion of the tube which will lie in the cervical canal. The vagina is protected from burning by a short tubular wooden speculum. The applications should not be repeated oftener than once a month, that amount of time being required to regenerate the mucous membrane. The period of time which elapses before the destroyed mucous membrane separates is an indication of the depth to which the cauterisation has extended; if it be merely superficial the interval is usually from six to ten days. The method is recommended for all forms of endometritis, subinvolution of the uterus, for disinfection of the uterine cavity, in cases of inoperable carcinoma of the body, in climacteric hæmorrhages, and in senile catarrh. In the two latter instances it may be used to produce total obliteration of the cavity of the uterus, and it is suggested that this may replace in some cases total extirpation of that organ. It is contra-indicated in cases of suspected malignancy, in affections of the appendages, and in cases of markedly rigid cervix (Pincus). Pitha records the results of 46 cases treated in Pawlik's clinic. 28 of the cases suffering from hæmorrhagic endometritis all recovered. In 10 cases of hæmorrhage following miscarriage decidual remains were first removed by the curette before applying the steam. These also recovered. The danger of the occurrence of unintentional obliteration of the uterine cavity appears to be greater after the application of steam than after curettage, but it is possible that such a result may ensure a more perfect recovery in certain cases such as those indicated by Pincus—viz., uncontrollable climacteric hæmorrhages and profuse senile catarrh. In all cases where intentional obliteration is carried out protection of the cervix is necessary in order to prevent closure of the cervical canal occurring before that of the body of the uterus. In some cases the use of steam would appear to be preferable to the use of the curette, as, for example, in cases of submucous and interstitial fibroids, where the operation of curettage may result in damage to the capsule of some of the tumours followed by sloughing. The reckless employment of such a powerful agent as steam may, however, be productive of much harm, and it is necessary, therefore, to utter a caution against its use except in carefully selected cases, especially where curettage has failed, and with a due observance of all the precautions necessary for the successful carrying out of the treatment. Our Berlin letter contains, it will be seen, an account of a paper on this subject by Professor Dührssen.

THE PRESS AND WATER ANALYSIS.

IT is idle to dispute the educational power of the press so long as it keeps its readers well and intelligently informed, but the lay papers now and again ill-advisedly attempt not only to record matters of a highly technical character, but also to serve up an interpretation of the same which may be very misleading and indeed serious. In an evening paper last week an analysis of a sample of the East London Company's water taken from a public standpipe was published and above the analysis and contents was printed a heading of a very sensational character, such as is calculated to inspire needless alarm and perhaps panic. We doubt whether the great bulk of newspaper readers understood one word of the analytical report, or if they did it would only be those sentences which would probably convey a wrong idea. The condition of things in regard to water-supply is quite serious enough without attempting to alarm the public with such statements as the following: "The sample of water was very impure and contained over two thousand microbes per cubic centimetre. Drinking such water might give rise to infectious or other diseases (typhoid fever, cholera, &c., are water-borne diseases). It is well known that cholera spreads more rapidly when the temperature is high and when the ground water is low. Consequently the present low condition of the company's water-supply is indicative of disease. It may be stated that the typhoid fever microbe can retain its vitality for a considerable period of time in water and it may multiply almost to any extent in that medium." Now these remarks are simply volunteered information, for this report says nothing of the existence of either the typhoid or the cholera bacillus. The object of the writer is clearly indicated in such sentences as, "It *may* multiply to any extent,"

Digitized by Google

and "The present low condition of the company's water-supply is *indicative* of disease." We do not believe that the quality of the water-supply up to the present is open to serious condemnation, otherwise we should find evidence of it in the health returns and there is no indication of any general prejudicial effect having so far been produced by the scarcity of the supply. It must be borne in mind that in spite of the reduced volume of water and of the flow of rivers yet in summer there are very powerful purifying agencies at work and, as a matter of fact, the maximum of purity of the London supply is invariably attained in the summer. Sunshine, doubtless, is the most important factor in this connexion. We might point also to the condition of things which prevails in southern Europe, as in Spain, where, in spite of the absence of rain for months together and the existence of insanitary conditions in the streets, the effect upon the public health is hardly as commensurate as might be expected with these conditions. There is no doubt that the intense sunlight serves as a powerful bactericide and compensatory factor. Such reports as we have pointed out do not help to tide over the difficulty and distress of a water famine, but, on the contrary, may bring about incalculable and perfectly needless harm, followed perhaps by insensate and groundless panic.

THE PLAGUE IN SIND.

IN a paper which was read at a meeting of the Bombay Medical and Surgical Society last July, Surgeon-General Bainbridge, I.M.S., gives a detailed account of the epidemic of plague which occurred in Sind in 1896–97. The communication was based on the author's official report bearing date Oct. 25th, 1897, a document which he describes as "the earliest complete account by a medical man of any outbreak outside the city of Bombay," but he further adds that the views therein set forth are in the main confirmed by the information which has since been recorded both in Sind and elsewhere. The first case of plague in Sind was reported at Karachi on Dec. 10th, 1896, and the last on July 27th, 1897, the total recorded cases during the period having been 6439 with 5182 deaths, or 80·4 per cent. The way in which Karachi became infected was not traced, but the importation of the disease by sea from Bombay was clearly possible as there was considerable traffic between the two ports and the three-day transit by steamer was free from restrictions "except in the case of vessels which had had a case on board or which carried no doctor." However it may have been introduced the plague spread slowly throughout the province, following the movements of infected persons, a quiescent interval of about one month in each fresh focus being usually observed before the bursting forth of the local manifestation. "This leads to the inference," continues the writer of the paper, "that the bacilli do not infect until they have gained a certain degree of potency and that they require certain media for their development. How infection takes place," he proceeds to say, "cannot at present, so far as I am aware, be demonstrated with certainty. It is known, however, that the infection (*a*) will prevail in certain dwellings and amongst certain families, whilst others in the immediate vicinity will escape; (*b*) that the spread of plague is associated with, or favoured by, overcrowding, dirt, and other insanitary conditions; (*c*) that contact with, or contiguity to, persons suffering with plague will, under certain conditions not exactly known, result in infection—probably the duration of the required exposure is proportionate to the numbers of the required microbes and to the resisting power of the individual; (*d*) that possibly plague may be communicated by infected clothing and other articles." In the same connexion he further observes: "I am unable to avoid the conclusion that infection occurs by inhaling the microbes when in close proximity to the sufferer, or in any place the air of which contains them in certain numbers." It is true that people who live under good hygienic conditions—even in plague hospitals where microbes must be present in the air of the wards—habitually escape the disease, but that may be either because fresh air, light, and cleanliness impair the potency of the germs or else because people so circumstanced "possess a certain power of resistance to infection." Surgeon-General Bainbridge does not believe in cutaneous inoculation as a common mode of infection, and with regard to the influence on the disease of climate and season he observes: "There seems no reason to suppose that, given the present sanitary conditions, plague may not originate and, if uncontrolled, spread in India at any season of the year, though certain climatic conditions may be more favourable than others to its development." That rats play an active part in carrying the plague from one part of a town to another he considers "fairly certain," but there is no proof that these animals infect human beings directly. The matter requires further elucidation, and the possibility of the plague germs being disseminated by means of soil carried on shoes, sandals, or even on bare feet, is also a point which should be determined. As may be supposed, the question of prophylaxis is dealt with at considerable length. The success of preventive measures depended entirely upon "the thoroughness and intelligence with which they were carried out by the individual officials concerned," but wherever these essentials were forthcoming the results were most satisfactory. The author looks upon the inspection of passengers at railway stations as a futile means of repression, calculated to effect a minimum of good in return for a maximum of trouble and expense. His sheet anchor is detention, with segregation of all arrivals from infected places, and, since the disease "almost invariably declares itself by symptoms within the fourth or fifth day from infection," the duration of the quarantine need never exceed ten days. The best way of dealing with localised outbreaks is by prompt evacuation. Referring to the Nussurpuri Camp, Surgeon-General Bainbridge is able to assert that "the mere removal of these people to a healthy place and wholesome environments sufficed, with imperfect measures of sanitary police, to stay an epidemic which would almost certainly have been extremely severe had they remained in their very unhealthy and overcrowded houses."

STREET HAWKING BY CHILDREN.

AT the meeting of the Manchester City Council on Sept. 7th a report from the Watch Committee dealing with the question of street trading or hawking by children and providing in the interests of the children for its supervision and control was unanimously adopted. There is plenty of evidence as to the demoralising tendency of this practice. The chief constable said that "street hawking in the centre of the city has a great tendency to lead boys to become thieves, loafers, and disorderly persons," and that the girls were led into degraded habits and eventually to utter ruin. "In the case of twenty-one girls, previously hawkers, all had taken to an evil life, and eight of them had become thieves in addition." Most of the children are the victims of their parents' vices. The chief constable reported that "in thirty-seven homes where boy hawkers lived in only one were sober parents found, in the remaining thirty-six either one was a drunkard or both." Powers are sought like those already possessed by Liverpool by which licences can be granted so that some effectual supervision may be exercised over those who obtain them and those found trading without licences can be properly dealt with and cared for. The provisions sought are powers to take a child trading without a licence or contravening its

Digitized by Google

regulations into custody without a warrant and to convey such child to a place of safety till he or she can be brought before a magistrate, who, if he is satisfied that the child has no proper home or that the parents are not fit custodians, will be able to commit such child in charge to some fit relative or other person named by the court until the attainment of the age of sixteen years or some shorter period, or to send the child to an industrial school or to suitable lodgings provided by the corporation. In no case, however, should the child even for the briefest detention be taken to a police-station or to a workhouse. Most probably arrangements can be made with the officers of the "Prevention of Cruelty Homes," or with that admirable institution the Boys' and Girls' Refuge in Strangeways. Almost anything would be better than the present state of things, which probably exists in London as well as Manchester. The nuisance caused by newspaper and race-card hawkers is intolerable. If licences were made obligatory they would get rid of the idle and vicious while the respectable hawkers would not be interfered with.

THE PATHOLOGY OF HERPES ZOSTER: "ABERRANT VESICLES."

HERPES ZOSTER should not be regarded as a disease of the skin but as a manifestation of disease of the nervous system —localised neuritis—which affects usually the posterior root and ganglion of a spinal nerve. But what is the cause of this neuritis? The etiology of herpes zoster has long been a moot subject. The most satisfactory hypothesis seems to be Landouzy's—that it is of infectious origin. Its definite course, occasional epidemic prevalence, and the immunity conferred by one attack support this view. Moreover, it may occur in known infections—tuberculosis, pneumonia, and syphilis, and (very rarely, it is true) in other exanthemata. In the *Revue de Médecine*, 1891, Adenot published a case in which zona developed in the tract of the radial nerve during measles. In THE LANCET, Dec. 26th, 1896, Dr. Maurice Paul published a case in which an attack of typhoid fever was ushered in by an outbreak of herpes zoster in the segmental area of distribution of the twelfth dorsal nerve. The neuritis probably is a toxic effect, and its localisation doubtless results from a diminished power of resistance of the affected nerve. That a general intoxication can produce this localised effect is proved by cases of arsenical herpes zoster. But the neuritis does not necessarily affect the root and it is not necessarily of infectious origin. Peripheral neuritis of traumatic origin—for example, pressure of an aneurysm on a nerve trunk—may give rise to herpes zoster. The most characteristic feature of herpes zoster is the distribution of the lesions according to cutaneous nerves or nerve roots. At a recent meeting of the Société Médicale des Hôpitaux M. Jeanselme and M. Leredde contributed a paper entitled "The Aberrant Vesicles of Zona." They state that in a number of cases careful examination shows disseminated over the entire cutaneous surface isolated vesicles quite similar to those of the zoster eruption. In 1888 M. Boulland published a case from the practice of M. Brissaud, and in 1893 M. Tenneson carefully studied the subject and stated that if the entire skin of patients affected with typical herpes zoster were examined every day these "aberrant vesicles" would be found nine times out of ten distributed irregularly at great distances from one another on all parts of the body. This statement by a well-known dermatologist is, to say the least, startling, for these vesicles have never been observed, as far as we know, in this country. Though described as similar to the ordinary zona vesicles they do not appear to be usually accompanied by pain, as they remain unnoticed if not looked for. At the next meeting of the society Dr. Giraudeau read notes of two other cases. A man had well-marked lumbo-femoral zona accompanied by malaise, anorexia, and fever. As the zona eruption was completing its development there appeared about thirty lesions over the whole body. Some were small papules, others were excoriated papules, and others were vesicles; some were isolated, and others were united in groups of two or three. There were three or four on the scalp, three or four on the face, ten on the back, and two or three on each upper limb. The erratic eruption was the seat of pains localised to the papules or vesicles but not propagated in the course of the nerves. M. Jeanselme and M. Leredde think that these aberrant vesicles bear out M. Landouzy's hypothesis. They certainly are evidence of the existence of a general and not merely local malady.

OFFICIAL INDEX TO THE REPORT OF THE VACCINATION COMMISSION.

THOSE who are acquainted with the ponderous blue-books containing the minutes of evidence, reports, and appendices which form the standing memorial of the seven years' labour of the Royal Commission on Vaccination cannot fail to have appreciated the excellent and compendious indexes which are affixed to the first four volumes of evidence and to have experienced keen disappointment at the absence of any such guide to the contents of the fifth volume and to the Final Report. This defect has been partially and somewhat tardily remedied by the issue of an index (obtainable from Messrs. Eyre and Spottiswoode, price 9*d.*) to the Final Report, compiled in the Medical Department of the Local Government Board. The index is strictly confined to the Report itself and does not include the lengthy Statement of the Dissentient Commissioners, whilst the bulky fifth volume of evidence still lacks this essential complement. However, students of the subject will be thankful to have their labours lightened by this instalment, which is admirably executed and embraces every one of the numerous points commented on in the Report. It shows, too, at a glance how wide was the field surveyed by the Commission and how thoroughly every subject material to the inquiry was handled by it.

SANITARY ADMINISTRATION IN PORTSMOUTH.

THE borough of Portsmouth had in the middle of 1897 an estimated population of some 182,585, and this fact, together with the importance of the town in other respects, is such as to justify its setting an example to smaller aggregations of people in the south of England as to sanitary equipment and administration. Unfortunately, this is apparently not the view taken by the town council of its duty, and some of the conditions revealed by Dr. A. M. Fraser in his last annual report are by no means "model." The isolation accommodation of the borough is presumably very deficient, and considerable difficulty has been experienced in preventing overcrowding of the wards; indeed, Dr. Frase reports that the accommodation is so small that it is often impossible to allow the proper amount of air space per bed. In a word the "accommodation is quite inadequate to the needs of the borough." We are glad to see that the medical superintendent refuses to allow overcrowding of the wards in order to admit more patients. Sanitary authorities have certainly no right to use moral suasion to bring patients to hospital and then to jeopardise their chance of recovery by overcrowding them. There is, too, a lack of "observation wards" at the hospital, and those who are familiar with the administration of fever hospitals know what unnecessary risks such absence entails. In the matter of house drainage and buildings by-laws, too, the sanitary authority seems on the horns of a dilemma. In consequence of a representation made recently to the town council by Dr. Fraser as to the absurd practice by which the Health Department was never consulted as to the drainage of a new house,

Digitized by Google

although that department was responsible for the drainage of every inhabited house, it was apparently resolved to bring into operation Section 24 of the Portsmouth Corporation Act, which enacts that "No new house shall be occupied until certified by the medical officer of health and borough engineer to be in every respect fit for occupation." The sanitary authority was, however, not yet out of the wood, for the borough engineer declined to certify that any house built under the by-laws then in force in the borough was necessarily fit for occupation! It would be certainly difficult, as Dr. Fraser observes, to bring forward a stronger argument for amending the old and obsolete by-laws of 1869 than that a house built in accordance with them should "be actually unfit to live in." We cordially endorse Dr. Fraser's wish that the end of 1898 may see this discreditable state of affairs remedied.

SAD MISADVENTURE WITH STRYCHNIA.

A MELANCHOLY incident occurred on Sept. 15th at the small village of Great Budworth, between Northwich and Warrington, in Cheshire. Dr. Gilbert Love, who is in practice there, had gone for a holiday, leaving Dr. W. Howard Clark as his locum tenent, and on the date mentioned this gentleman, who had been in the village about a fortnight, walked from Northwich, a distance of four miles. Arriving home much fatigued, and also suffering from the unwonted heat of the weather, he went into the surgery and afterwards sat down to dinner with Dr. Love's sister-in-law, who was in charge of the house, but before taking anything he complained of feeling cramp all over his body, became unconscious, and died in a few minutes. On the surgery being entered a bottle of strychnine was found on the table, together with a medicine bottle in which was the residue of a draught containing strychnine, gentian, and ammonia. At the inquest, which was held on Sept. 17th, a medical friend of the deceased stated that he had seen him take a similar mixture as a pick-me-up and the evidence showed that between half a grain and three-quarters of a grain of strychnine was found in the stomach. Letters were read in court proving that not long before his death the deceased was in good health and spirits. The jury returned a verdict of "Death from misadventure due to the taking of an overdose of strychnine." Much sympathy will be felt for the friends of Dr. Clark who was twenty-six years of age and graduated as M.B. at Aberdeen University in 1897. The case is an impressive reminder of the need for care in the dispensing of poisons.

THE SALIVARY DIGESTION OF STARCH.

THE digestion of starch is a process which is common to man and all herbivora, for starch is widely distributed in the tissues of plants and constitutes one of their most important constituents, second only to protoplasm and chlorophyll. It is composed of granules, varying considerably in size, from the large, concentrically laminated, oval bodies seen in "tous les mois" and in potatoes, to the minute angular granules in rice. Starch is insoluble in water and consequently to enable it to be absorbed after its entrance into the alimentary canal it is necessary that it should undergo some chemical change. It has long been known that the change in question is its conversion into sugar, which is accomplished in the first place by the ptyalin or diastatic ferment contained in the saliva and subsequently by the action of ferments having a similar action contained in the pancreatic and intestinal juices. The effect of the ferments is the addition of a molecule of water to the starch molecule, by which it is converted from an insoluble substance into a soluble sugar. Dr. Aitchison Robertson has recently undertaken a series of researches on the process of amylolysis by ptyalin in mixed diets which has not hitherto been carefully studied. His results are of considerable interest, since they have a direct bearing on the selection of a proper diet for invalids and infants. There are not a few persons who suffer from amylaceous dyspepsia, and to aid such patients in their digestion of the starches many forms of diastase have been recommended, such as malt, maltine, malt extracts, and taka-diastase, but there are objections to the use of these agents since they interfere with the digestion of the proteids and have a tendency to set free rapidly a large quantity of sugar in the stomach. Dr. Robertson commenced his researches by endeavouring to ascertain the quantity of saliva which he secreted with different articles of diet by weighing them, masticating them, and then instead of swallowing them ejecting and re-weighing each bolus. He found that taking 6 oz. of porridge for breakfast with milk leads to only a small salivary secretion, not amounting to more than 3 or 4 grammes. After eating the porridge, bread, butter, and cold meat to the amount of 5¼ oz. were chewed, and it was found on re-weighing that about 50 grammes of saliva had been secreted. In the interval between breakfast and dinner the quantity of saliva secreted during four and a half hours amounted to from 50 to 60 grammes. During dinner, consisting of 7½ oz. of meat, potatoes, and rice, followed by milk pudding, from 20 to 30 grammes of saliva were secreted. In the interval between dinner and tea there were from 35 to 55 grammes. At tea, which consisted of 2¾ oz. of bread and butter, from 47 to 53 grammes of saliva were added. Between tea and supper from 60 to 70 grammes. Supper consisted of 2¼ oz. of plain bread and butter and 5 grammes of cheese, leading to the secretion of from 40 to 45 grammes of saliva. Between supper and bedtime from 30 to 40 grammes were secreted. The total amount per diem was consequently 400 grammes. He found that rinsing out the mouth with tepid water greatly promotes the flow of saliva, hence tea, though it contains tannin, rarely causes amylaceous dyspepsia, the excess of ptyalin counteracting the action of the tannin. Brandy, whisky, and beer are sialogogues, as also are sweets. Mechanical irritation of the buccal mucous membrane and movement of the jaws as in speaking cause an increase of saliva. Dr. Robertson found that there were considerable daily variations. He made many experiments, for the details of which reference must be made to the original paper in the *Journal of Anatomy and Physiology* (vol. xxxii., p. 615), on the effects of saliva on mixtures of starch with different food constituents and beverages, which is, of course, quite different from the quantity of saliva secreted. Amongst other conclusions he satisfied himself that porridge and milk forms a more digestible compound as far as amylolysis by saliva is concerned than other combinations of oatmeal; that the more broken-down and moist the starch particles are the more rapid and extensive is the amylolysis. Bread in a light and spongy condition is more rapidly acted upon by saliva than when less spongy, though the ultimate digestion is not more complete. Milk has a retarding influence on the salivary digestion of starch in bread, whilst broth has little or no effect. Tea and coffee have an inhibitory influence on amylolysis, but cocoa has little or none. Beer promotes the salivary digestion of starch; alcohols, speaking generally, retard it even in dilute solution, wines appearing to have this influence chiefly owing to their acidity.

THE ENNISCORTHY UNION.

AT the recent Congress of the Royal Institute of Public Health held in Dublin Mr. Thomas Kelly of Enniscorthy read a paper in which he made some reflection upon the pauper nurses employed in the Enniscorthy Workhouse. The

Digitized by Google

matter came up at a meeting of the Enniscorthy guardians on Sept. 8th and Mr. Kelly was called upon to apologise. This apparently he has not done. Now we know nothing personally of Enniscorthy, still it must be allowed that scandals in connexion with the nursing of paupers by paupers undoubtedly do exist in Ireland and for the matter of that in England and Scotland too. Mr. Kelly was quite right to point them out. Possibly he described them in rather more florid language than the circumstances would warrant, but on this point it is impossible for us to decide. The chairman of the meeting (Mr. H. H. O'Neill) is reported as saying :—

I have no objection to see medical officers paid well if there was a uniform fee or tax, but they get everything they ask. This should no longer exist. The people are getting unfettered, a new era is dawning, liberty is approaching, and we will no longer tolerate in the future what we have tolerated in the past.

If medical officers in Ireland get everything they ask for it is more than they do in England.

THE ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

IN drawing attention last week to the formation of a society in the county of Durham having for its object the dissemination of knowledge concerning tuberculous diseases and their prophylaxis we did not perhaps do full justice to the association founded in London this summer, and of which the offices are established at 20, Hanover-square, W. We understand that this association has already enrolled a large number of members, and that steps are being taken to make its objects more widely known by means of a public meeting to be held probably in the course of next month. We have pleasure in publishing the annexed statement of the senior association's objects and views, which clearly shows that the organisation of this association may well claim priority in this laudable enterprise :—

1. OBJECT.—The prevention of tuberculosis.
2. MEMBERSHIP.—The Association consists of ordinary and of life members. The subscription of ordinary members is 5s. annually. Life members give a donation of 5 guineas.
3. METHODS.—I. The education of public opinion and the stimulation of individual initiative by means of—
(a) A central bureau for the collection and distribution of information as to modes of diffusion of tuberculosis and measures of prevention.
(b) The circulation of pamphlets and leaflets setting forth in plain language the results of scientific investigation of the above points.
(c) Public lectures by men approved by the council; addresses at congresses and other public gatherings.
(d) Coöperation with other societies having for their object the promotion of public health.
(e) The coöperation of the public press.
(f) The holding of periodical congresses and the issue of an annual report.
(g) The promotion of the establishment on a self-supporting basis of open-air sanatoria for tuberculous patients.
II. The influencing of Parliament, county councils, boards of guardians, and other public authorities on matters relating to the prevention of tuberculosis.

THE WATER-SUPPLY OF MELBOURNE.

IN a report on the condition of the drinking-water and the necessity for having the waste-pipes from houses disconnected from the drains into which they lead Dr. D. Astley Gresswell, of the Board of Public Health, Victoria, gives an interesting sketch of his efforts to improve the quality of the public water-supply. In 1894 he drew the attention of the Board to the facts that almost throughout that colony the water provided for drinking purposes was directly derived from open catchments, that necessarily it contained a large quantity of organic matter, that in most instances it was open to very gross pollution, that with only rare exceptions it was supplied unfiltered, and that there was a close relationship between impure water and diseases such as diarrhœa, dysentery, typhoid fever, and hydatids. During the past seven years the Board has persistently brought under public notice the need for care as to the condition of the water used for drinking and has strongly recommended the boiling or effective filtration of all such water. Filtration on the premises of the consumers is being more and more adopted, with a corresponding improvement in the quality of the water. This holds more particularly in connexion with the Railway Department, the Education Department, the Government offices, private schools, hotels, coffee palaces, restaurants, factories, and public buildings, while effective filters in large numbers have been affixed to service-pipes supplying private families. At the State School numbered 583, in Punt-road, Melbourne, Mr. W. H. Powell, the head teacher, some time ago, by means of voluntary subscriptions and the proceeds from a concert, had four large-sized Jeffery filters with a 350-gallon iron tank installed at a cost of about £12. Beetles in enormous numbers and snakes in large numbers, as well as rabbits and other animals pass into the conduits and reservoirs from the open catchments and dying give rise to much contamination of the water. Eels also are found in the pipes within the city; Dr. Gresswell has one in his office measuring 33 in. in length and 7 in. in girth. Another cause of pollution is the entrance of foul surface water from the streets into the mains through the fire-plugs. A small fish (Galaxias) has for years been found in large numbers in the mains of the Adelaide Waterworks, and has given rise to numerous complaints owing to blockage of service-pipes and putrefaction of the fish. The appendices to Dr. Gresswell's report include reports on an occurrence of typhoid fever by Dr. Thomas Gray, assistant medical inspector, and Dr. James Jamieson, officer of health of the city of Melbourne.

THE DANGERS OF ICE-MAKING.

THE awful disaster reported from Glasgow must be counted as one amongst the many dangers which a spell of hot weather may bring in its train. The demand for ice has risen by leaps and bounds, and doubtless the increased pressure upon the working capacity of a large freezing machine at an ice works in Glasgow was responsible to some extent for the explosion of the apparatus which ultimately killed three men and injured several others. The freezing plant was constructed on a well-known principle, ammonia being employed as the agent for producing cold by evaporation. In its simplest form the apparatus consists of an iron boiler into which a quantity of a saturated solution of ammonia is placed. On heating the liquid the ammonia gas is driven out of the solution and travels into a receiver where it liquefies under the pressure attained. The heat is then withdrawn and the boiler cooled, when the reverse process takes place. The water absorbs the ammonia, the evaporation of the liquid gas in the receiver produces intense cold and thus converts into ice the water which is placed in it. The process is continuous. Since a saturated solution of ammonia will contain from 600 to 700 times its volume of gas the effect of the bursting of a large machine may be to some extent imagined. In the disaster already referred to there was no fire at all, and the fire-engines which arrived on the scene soon after the explosion were powerless to act, and the crowd which had gathered could not approach the scene on account of the overpowering ammonia gas. It was a long time before a search could be made, but by means of drenching the premises with water and the use of respirators soaked in vinegar a search was at length made and the body of the unfortunate manager was recovered. We presume that the ammonia mothod affords certain advantages for the purpose, but carbonic acid gas may also be used in a similar way. In the case of explosion, however, the carbonic acid would not be so deadly and overpowering as ammonia gas. This fatal occurrence should emphasise the need of great care

Digitized by Google

being taken with domestic freezing machines which do their work on the same principle—that is, the alternate expulsion and reabsorption of ammonia. We do not remember a case occurring before, so it may be assumed that the process is fairly safe but that owing to a structural defect or perhaps blocking of the pipes the unfortunate explosion took place.

THE OPENING OF LABORATORIES OF PHYSIOLOGY AND PATHOLOGY AT LIVERPOOL.

IN our issue of Sept. 17th we gave a list of some of those who are to be present at the opening of the new Thompson-Yates Laboratories of Physiology and Pathology, on Saturday, Oct. 8th, at Liverpool. Additional names are those of the Bishop of Liverpool, the Vice-Chancellor of the University of Cambridge, the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh, and Sir William Turner. At three o'clock Lord Spencer, Chancellor of the Victoria University, will confer the degree of Doctor of Science upon Lord Lister in St. George's Hall, after which at half-past four the laboratories in University College will be formally opened and inspected. After the ceremony tea and coffee will be served at the College.

SECONDARY HÆMORRHAGE FOLLOWING THE REMOVAL OF POST-NASAL ADENOID VEGETATIONS.

IN the *Boston Medical and Surgical Journal*, May 19th, 1898, Dr. W. Preble writes on this very unusual complication. He removed vegetations from a girl aged eleven years. The bleeding was not severe. The operation was quite successful and nasal breathing was restored. But on the seventh day a sudden hæmorrhage occurred and the girl was carried into the house fainting. Under cold syringing the bleeding stopped. It recurred and was stopped by plugging the posterior nares. On the eighth day a sudden gush of blood came on and she died before assistance could be rendered. There was no history of hæmophilia. Dr. Preble has collected 21 cases of serious primary hæmorrhage after this operation (of which 4 proved fatal) and 5 cases of secondary hæmorrhage. Of the latter 3 of the patients were French and 2 were Danish. There does not appear to be any case of secondary hæmorrhage recorded in English literature.

THE TRAVELS OF PROFESSOR KOCH.

UNDER the title of "Reise-Berichte" Professor Koch has published[1] the text of the reports furnished by him from time to time during the eighteen months of his "roving commission" in Africa and India, where he was engaged in investigating the rinderpest, the plague, and malarial and other affections. They form an interesting volume in which the main lines of his inquiries and their results are described with his customary lucidity. Professor Koch was invited by the Cape Government to investigate the rinderpest which had invaded the colony from the districts north of the Zambesi. He arrived at Cape Town on Dec. 1st, 1896, accompanied by his assistant, Dr. Kohlstock. He established himself at Kimberley, in the vicinity of which the rinderpest was rife, and by the end of March, 1897, was well advanced in his laboratory work upon a method of protective inoculation for the disease. He was then requested by the German Government to proceed to Bombay to take charge of a scientific commission which had been despatched thither to investigate bubonic plague. Leaving his work on rinderpest immunisation — already practically complete — in the hands of Dr. Kohlstock and Dr. Turner, the former being subsequently replaced by Dr. Kolle, Professor Koch set out for Bombay. When he arrived on May 1st he found that the German Commission under Professor Gaffky had nearly finished their labours, and by the end of June the Commission returned to Germany. Professor Koch, however, had in accordance with instructions to proceed to German East Africa to investigate a disease resembling plague which had appeared there. Here, he says, he found a rich field for work, and whilst Dr. Zupitza proceeded inland to collect material on the malady in question he busied himself with studies on tropical malaria (which we propose to notice at greater length in a future issue), Texas fever, and the Tsetse or Surra disease of cattle. It was in February, 1898, that he received at Daressalam, where he had established himself, materia which enabled him to declare the cases seen by Dr. Zupitza to be true bubonic plague. His labours were now at an end and on May 20th he returned to Berlin. The reports now published must, he says, be considered for the most part as preliminary to more detailed accounts which he hopes to produce when occasion serves. We fear that the new commission he has received to study malaria may delay the appearance of these more extended writings, and therefore it is all the more satisfactory to have the present accounts of scientific work written at the time when the researches were in progress.

[1] Reise-Berichte über Rinderpest, Bubonenpest in Indien und Afrika, Tsetse oder Surrakrankheit, Texasfieber, Tropische Malaria, Schwarzwasserfieber. Von Robert Koch. Berlin: Verlag von Julius Springer. (Reports on Rinderpest, Bubonic Plague in India and Africa, Tsetse or Surra Disease, Texas Fever, Tropical Malaria, and Blackwater Fever. By Robert Koch. Berlin: Julius Springer.) 1898. Obtainable from F. Bauermeister, foreign bookseller, Glasgow. Price 2s. 9d.

NON-POISONOUS MATCHES.

ONE undoubted way of preventing phosphorus necrosis in match factories would be to eliminate altogether the yellow phosphorus in the manufacture of the match-head. The difficulty is, however, to find a substitute which, like the ordinary phosphorus match-head, will strike anywhere. The safety match will, of course, not do this, the means of producing ignition being the rubber on the box which contains non-poisonous or amorphous phosphorus. In other words, the safety-match tip contains the elements of combustion while the rubber contains the excitant. We are not prepared to admit that the entire adoption of this system would be a source of serious inconvenience to the public. However, several persons, prompted by the publication of the recent cases of phosphorus poisoning in certain match factories, have been seeking for a composition which will do away entirely with the use of poisonous phosphorus while at the same time it will strike anywhere. No quite new direction in the preparation of such a match appears to have been suggested. The published composition of one in particular is the following: chlorate of potash, whitening, plaster of Paris, ground glass, glue, and amorphous phosphorus. There is reason to believe that red or amorphous phosphorus is not poisonous, for a case is recorded in which a dog took as much as 7 oz. in twelve days and remained without showing any signs of being poisoned. The only novelty in the above composition appears to us to be the use of special diluents like whitening and plaster of Paris, which reduce the energy of the otherwise violent action between red phosphorus and chlorate of potash. These latter substances indeed form undiluted a very powerful and dangerous explosive. It is this mixture which is used in toy caps or the French *amorces*. By attenuating the mixture with an inert powder such as whitening it is probably rendered less active and therefore safe, while in the form of a dry match tip it is said to strike anywhere. Now that public opinion has been stirred in this matter it is probable that attention will be given to non-poisonous matches with the view of dispensing with the ordinary yellow phosphorus, the use of which involves unhealthy conditions to the operatives engaged in ordinary match-making. We have ceased

Digitized by Google

to look upon the match in the light of a luxury as in the flint, steel and tinder days of our forefathers, but the new match must be satisfactory in all points before the public will take kindly to it.

THE MALARIA COMMISSION.

THE Commission for investigating the various questions associated with malaria which has been appointed by the Colonial Office and the Royal Society consists of the following members:—Dr. C. W. Daniels, of British Guiana; Dr. S. R. Christophers, of University College, Liverpool; and Dr. J. W. W. Stephens, John Lucas Walker Student in Pathology in the University of Cambridge. Dr. Christophers and Dr. Stephens will proceed almost immediately to Pavia to work in the laboratory of Professor Golgi and thence to Rome to work in Professor Cetti's laboratory. The Commission will eventually proceed to Africa, when its first work will in all probability be to determine the clinical varieties of malarial fevers occurring there.

LECTURES AND DEMONSTRATIONS FOR SANITARY OFFICERS AND STUDENTS.

A COURSE of lectures has been arranged by the Sanitary Institute for the special instruction of those desirous of obtaining knowledge of the duties of sanitary officers and of other persons desirous of obtaining a practical knowledge of sanitary requirements and regulations. The course will consist of seventeen lectures delivered at the Parkes Museum, Margaret-street, Regent-street, W., and will commence with a free introductory lecture on Oct. 17th. The lectures will be given at 8 P.M. every Monday, Wednesday, and Friday from Oct. 17th to Nov. 25th. The lecturers for October are Sir Douglas Galton, Dr. Louis Parkes, Dr. Herbert Manley, Dr. W. A. Bond, Professor A. Bostock Hill, Dr. J. F. J. Sykes, and Professor W. H. Corfield. Inspections and demonstrations have been arranged in connexion with the lectures, and will include visits to disinfecting stations, dairy premises, municipal depôts, artisans' dwellings, offensive trades, waterworks, common lodging-houses, sanitary works in progress, refuse and sewage disposal works. There will also be demonstrations of meat inspection and diseased meat. The museum of sanitary appliances and the library will be opened free to students attending the course. The fee for the course is £2 2*s*. Application should be made at once to Mr. E. White Wallis, secretary of the Institute, Margaret-street, W.

THE PUBLIC HEALTH ACT AND ENTERIC FEVER.

AT the meeting of the Sanitary Committee of the Louth Town Council, held on Sept. 8th, the sanitary inspector reported that on August 26th Mr. G. Briggs had been notified by Mr. G. Gresswell as suffering from enteric fever and that the said Mr. G. Briggs had on Sept. 3rd wilfully exposed himself while suffering from a dangerous and infectious disease without taking proper precautions against the spread of infection in certain streets of the town. It was resolved that proceedings should be taken under Section 126 of the Public Health Act of 1875 against Mr. Briggs. At a monthly meeting of the town council, held on Sept. 13th, this report of the committee was submitted for confirmation and a long discussion arose about the above-mentioned case. Dr. Best, a member of the town council, said that in his opinion it was dangerous to be in a railway compartment with a person suffering from typhoid fever. The medical officer of health said that Dr. Albert Gresswell had told him that there was no doubt about the diagnosis. On the other hand, the Mayor said that Mr. George Gresswell had written and said that there was no danger in the man being out and that Dr. Albert Gresswell had called upon him (the Mayor) and had said the same thing. Therefore he thought that if they prosecuted Mr. Briggs the magistrates would not convict. Eventually the matter was referred back to the committee. We should say that Mr. Briggs probably did a great deal more harm by going out to himself than to anyone else. For all that, a person going about whilst suffering from typhoid fever is undoubtedly a potential source of infection and it should be made plain that "exposure" in the sense of Section 126 of the Public Health Act of 1875 is illegal and should be punished. The danger, of course, of spreading infection is infinitely less in a case of typhoid fever than in scarlet fever or typhus fever, but it exists for all that.

HEALTH RESORTS AND INFECTIOUS DISEASE.

THE public of Great Britain, and doubtless to a greater degree the public of other countries, still betray an almost criminal slackness as to the sanitary conditions, equipment, and administration of the "health resorts" to which each recurring summer the holiday-makers betake themselves. Business men who, as members of their urban or rural district councils, have, or ought to have, sanitary matters constantly before them, give not a thought to the drainage, the water-supply, or the isolation accommodation of the "health resorts" to which at no small expense they send their wives and their children. Much less do they take the trouble to ascertain whether infectious diseases may be prevalent in the locality, or if, perchance, the previous occupants of the room or lodgings have suffered from such diseases. What a reform might be brought about in the sanitation of many of our so-called "health resorts" if, before selecting his annual camping-ground, the head of the family were to ask for certain information from the local medical officer of health. Even if this course did not commend itself to him he might, as Dr. Niven points out in his recent quarterly report on the health of Manchester, consult the Registrar-General's quarterly return for information as to the deaths from infectious disease in each of the principal watering-places of Great Britain, and thus avoid localities where these diseases have been recently prevalent. If parents will not take these very elementary and easy precautions they must be prepared at times to pay the penalty of their negligence.

THE VENTILATION AND WARMING OF DORMITORIES, WORKSHOPS, ETC.

AN important report to the Local Government Board has recently been issued in the form of a blue-book on this subject. The inquiry, which was obviously a practical one, was undertaken by Mr. W. N. Shaw, M.A., F.R.S., Lecturer in Experimental Physics in the University of Cambridge. The object of the inquiry was to ascertain whether, where improvements were found to be necessary, they could be carried out in such form that general principles might be laid down applying to the various requirements to which the guardians or managers to whom the schools belong might give effect with the assistance of their respective architects. The observations referred to dormitories, workshops, and other rooms in certain of the Metropolitan Poor-law schools. The appendices contain details of calculations and full particulars and notes as to dimensions, aspects, &c., of the rooms indicated. The report suggests not only the need of improvement and attention to provisions already made, but the possibility of applying better principles without any serious structural alterations. The recommendations in many instances are extremely simple; in other cases it is remarked that ordinary

Digitized by Google

provisions, simple though they may be, are very often ignored. Mr. Shaw incidentally refers in the section on Infirmaries to our own inquiry into the plenum system of ventilation which is now in practice at the General Hospital, Birmingham.[1] Speaking of this system he says that it has had its failures and also its successes, but assuming that the building is under careful supervision by an architect and engineer of repute a very successful result would seem certain, "and it is probable that some form of the mechanical system will be extensively used in the future." The bulk of the report, however, relates more to the requirements and existing conditions of the metropolitan Poor-law schools than to buildings on the scale of a hospital or infirmary. New schemes of ventilation and warming can only be adequately applied to new buildings or buildings in course of construction, but Mr. Shaw's report contains a mass of material which should be a useful guide to many who have to contend with archaic buildings, and therefore with all sorts of structural obstacles in attempting to make any system of ventilation and warming satisfactory.

THE first annual dinner of the North-West London Clinical Society will take place on Thursday, Oct. 27th, at the Café Royal, Regent-street, at 7.30 P.M. The President, Mr. Victor Horsley, F.R.S., will take the chair and will give the annual address, on "The Rational Treatment of Goitre," at 6.30 P.M. at the same place.

AN interesting link with the past has been severed by the death last Saturday, at the great age of ninety-five years, of Mr. John Lettsom Elliot, the "father" of the Athenæum Club. He was the grandson of Dr. Lettsom, the founder of the Medical Society of London, and one of the original group of members of the Athenæum.

THE introductory lecture at the opening of the session of the Royal Veterinary College will be delivered by Professor Shave, F.R.C.V.S., on Monday, Oct. 3rd, at 1 P.M. The chair will be taken by Major-General Sir Henry Ewart, K.C.B.

SIR JOSEPH EWART, M.D. St. And., has declined the invitation of the Liberal party in Brighton to be their candidate for Parliament at the next election.

SOME EXPERIENCES OF AN AUSTRALIAN COUNTRY GENERAL PRACTITIONER.

BY LEONARD W. BICKLE, M.R.C.S. ENG., L.R.C.P. LOND., F.R.C.S. EDIN.

JUST after having completed arrangements to take up life in Adelaide, the capital of South Australia, after many years' experience as a country practitioner, I have jotted down short notes of some of the more important surgical cases which have been under my care. These notes will serve to show that successful surgical work can be undertaken in the country without the appliances of any hospital, but I am bound to admit that the anxiety and fatigue entailed is far beyond the remuneration obtainable. All the amputations (and four of them were in men over sixty-five years of age) were done with the simple assistance of one other medical man to give the anæsthetic and my groom as dresser. One cholecystotomy was performed single-handed with only the help of a village untrained nurse, and a cholecystectomy with the help of one qualified man and a fourth year's student in addition to my groom to hand the instruments. When home on a visit to the old country last year I was asked by more than one old friend to publish brief notes of some of my cases and it is on their suggestions that I have drawn up this paper. In three cases I had the helpful assistance of a trained nurse, for others the devoted attention of relatives and close friends, and in many others the assistance of the ordinary untrained nurses, who were willing to learn and then act.

Cholecystotomy twice, followed by cholecystectomy on the same patient; recovery.—The patient was a woman about thirty-eight years of age. She had had repeated attacks of gall and renal colic and constant shivering attacks with occasional jaundice and was said to have brought up matter and blood several times with great relief (the vomit was never seen by me). Occasionally a gallstone was felt in the flaccid state of an enlarged gall-bladder, it was not to be felt when the bladder was tense. After a time it was impossible to feel it. A large rounded tumour, reaching to below the level of the umbilicus, was found when next the patient was seen after some months' interval. This moved up and down with the respirations and was so tense as to suggest that it was solid. Her sufferings being now severe and constant an operation was consented to. On opening the abdomen a tense thin-walled cyst was seen. Enough thin opalescent fluid was drawn off to allow the walls to be sewn to the edges of the abdominal incision. The cyst was then freely opened and found to contain another tumour. This was incised and found to be thick-walled and full of pus. At the bottom was found a large gallstone of the size of a small nutmeg. The wall was secured to the skin wound by sutures; after a while the fistula closed and the patient felt comfortable. Symptoms of gallstones recurred and one afternoon I injected cocaine and opened up the scar; another stone was felt, this time just in the duct. Cauticus attempts at dividing the commencement of the duct having failed I gave chloroform and by the help of a bullet forceps and a gimlet succeeded in removing piecemeal the stone, which was rather larger than the former one. The sinus closed. After a while attacks of gall colic recurred. The wound was opened up but no further stone was felt. There was a valve-like growth over the entrance to the duct allowing bile to come in, but obstructing the return flow to the bowel. Scraping this away gave temporary relief. Finally, the fistula kept patent. The constant outflow of bile and mucus was very troublesome. Then blood and matter were often discharged. The condition was miserable in the extreme. The risks were explained to, and accepted by, the patient. On Dec. 4th, 1893, I opened the abdomen below the fistula. No stone could be felt in the duct. The walls of the gall-bladder were greatly thickened (over ½ in.). The bladder was laid open and a probe passed right down the duct. Using this as a guide, the bladder was dissected off the liver and the duct was ligatured and divided. Bile came from the wound for three or four days after the operation and then ceased. The patient made a good recovery. Now (August, 1896) she can do her household work and walk several miles. There is some amount of ventral hernia; with the exception of the trouble required in adjusting the belt for this, life is as enjoyable as before it was miserable.

AMPUTATIONS.

1. *Through the knee-joint; recovery.*—The patient was a man, aged seventy years. He was seen in consultation, suffering from a compound fracture below the knee caused by a kick from a horse. There was uncontrollable hæmorrhage. The patient had never made a will; we had therefore to act as lawyers before proceeding with the operation. At 1 A.M. in the small cottage bedroom and by the light of a kerosene lamp and candle I amputated through the knee, which was partially ankylosed from rheumatism. The patella was excised for fear of prolonging the operation too long at that age by sawing through it. The popliteal artery stood out like a pipe stem from atheromatous changes. The patient was out and about in less than one month after. There was no secondary hæmorrhage.

2. *Circular through the lower one-third of thigh.*—The patient was a man, aged sixty-five years. He had been bedridden for three years with a huge ulcer of the leg exposing several inches of tibia and fibula. The patient was in the habit of cauterising the growth with a red-hot poker. The skin was affected above the knee, hence operation so high up at that age. It was dressed with iodoform and vaseline on lint and salicylic wool. Union was by first intention. Sixteen days after the operation the drainage holes were so far healed that no further visits were paid.

[1] See THE LANCET, May 11th, 1895.

Digitized by Google

The patient died from cystitis some years after. In this case I had the assistance of a trained nurse.

3. *Osteo-myolitis of the tibia; ? metastasis; amputation through the lower one-third of thigh; lardaceous changes; albuminuria; recovery.*—The patient was a girl, aged ten years. The child had been kicked on the shin by a schoolfellow when she was suffering at the time from cold. When seen next day there were fever, cough, pneumonic expectoration, tubular breathing, and fine crepitation and dulness over the upper half of the left lung. There was a tender spot on the skin. Two days later the lung signs had all cleared. The leg was very tender and there was a localised swelling. Chloroform was given and an incision was made down to the bone; puriform fluid with oil globules escaped. The condition extended and numerous free incisions were made under chloroform two days after. The whole shaft of the tibia was necrosed. The question of removing it entire through the periosteum was debated, but friends would not consent. The patient was going downhill; amputation was refused. Quite half the tibia was removed as a sequestrum. Both knee- and ankle-joints were involved. With albuminuria present and the condition desperate friends consented to amputation. I amputated through the lower third of the thigh by oval skin-flaps and circular division of muscles. For twenty-four hours the patient hovered between life and death, only kept up by nutrient enemata; then youth prevailed. On the twelfth day after the amputation the patient was well enough to be out on a couch and dressed, union having taken place by first intention. There was no rise of temperature, although the operation was performed in the room saturated with the effluvium of bone pus for weeks. The dressings were of iodoform and salicylic wool. The albumin cleared away and the patient is now well and strong.

4. *Amputation of the forearm.*—The patient was a man, aged sixty-seven years. The hand above the wrist was mangled off by a chaff-cutter. The patient was seen on a cottage sofa in a small room. As I pulled out the sofa it collapsed, so a box was hurriedly brought in from a small shop near and the couch was propped up. I performed the amputation kneeling. The medical man who gave chloroform was one of the old school and had not seen a drainage-tube used; he thought it would act as a *foreign body*. Now, ten years later, the modern (?) idea is to use a drain-tube as little as possible for the very reason given by my esteemed old friend. Union was by first intention.

5. *Disease of the metacarpo-phalangeal joint in the left index finger.*—The patient was sixty-one years of age, the subject of chronic fibroid phthisis. The finger and half the metacarpal bone were removed. Union was by first intention. There was no recurrence of the disease in any other joint.

6. *Amputation of the breast.*—The patient was a very stout woman, aged about fifty years, with a cystic sarcoma. There was some slight suppuration in the centre; the other parts healed by first intention. Four years later the scar was freely moveable; there was no thickening. The patient is now well.

7. *Amputation of the cervix uteri.*—The patient was a married woman, aged about fifty years. She had had no children, but had had one early miscarriage in the first year of married life. Conical cervix with pin-hole os projected from the vulva; it was removed by Paquelin's cautery. There was a long-standing history of spinal trouble. Beyond relief from removal of the protruding cervix no other benefit followed operation.

OVARIOTOMY.

The patient had a large multilocular tumour apparently of the right ovary, a tense cyst projecting into Douglas's pouch—fixed on vaginal examination. At operation the tumour was found to be of the left ovary twisted on itself. The right was small but cystic and firmly adherent to the under surface of the upper cyst. On reducing the size of the lowest cyst by tapping the adhesions between it and the pelvis were separated with rather free hæmorrhage. Several inches of bowel were adherent to the upper and larger cyst and were dissected off with care. A glass drainage tube was used. The rest of the wound was closed by silkworm gut and silk sutures. The pedicle was tied by a Staffordshire knot. The right ovary and tube were also removed. On the fourth day after the operation the opening for the drainage tube (which closed directly the tube was removed on the second day) burst open and the patient and nurse were both alarmed. The noise of air passing in and out was like the breathing through a tracheotomy tube. After this recovery was uneventful. She went to her home on the twenty-eighth day. She now rides horseback with comfort. There is no trace of hernia. The abdominal wound was supported with broad strips of window plaster. Menstruation came on four days after the operation. Although both ovaries were removed it has continued regularly and painlessly every month since from a portion of the tube or third ovary. In this case I was well off for assistance, three other medical men being present. (I also had the assistance of a trained nurse, who was most unremitting in her care.)

GUNSHOT WOUNDS.

1. *Right lung.*—The patient was a youth, aged about sixteen years, who received the whole charge of a muzzle-loading shot gun in the back, the gun being only a few feet away. When seen he was in a pitiable condition. There was a large hole in the back capable of admitting two or three fingers. There were numerous small holes around. No attempt was made to find the depth of those to the left of the spine. There was much general emphysema; breathing was very laboured. His distress was relieved by small doses of morphia and he gradually came round. The lung expanded again. The patient was very indiscreet; three weeks after the accident he completely disobeyed instructions. The result was a rigor and pneumonia of the injured lung. Effusion followed. He was tapped several times; then the fluid became purulent. A portion of rib was excised for free drainage. He recovered and is able to do ordinary work. There is a lower scar at the site of operation which still discharges at times. Roentgen rays will be used at the first opportunity. A few shot are to be felt under the skin over the front of the right chest; these cause no inconvenience and are therefore left.

2. *Left wrist; medico-legal aspect of case.*—The patient declared that the gun slipped and went off in the fall. On the flexor surface of the wrist was a clean-cut circular wound blackened by powder. On the dorsal surface there was a jagged wound—that of exit. The tip of the right thumb and the end of the nail were blown off. Evidently the patient was leaning with his wrist over the barrel and the tip of the right thumb just overlapping the barrel. The trigger was probably pulled in rubbing one leg against another. The lower end of the radius was blown to fragments, thirteen pieces of various sizes being removed and upwards of sixty shot. The patient was very troublesome. He had two or three attacks of secondary hæmorrhage but eventually recovered.

HERNIOTOMY.

The patient was a woman, over eighty years of age, suffering from strangulated umbilical hernia. She was seen late in consultation one Saturday night. There was a history of strangulation from the Thursday morning previously. Pain had ceased half an hour before my arrival. On the off chance operation was proceeded with. A small knuckle of bowel was tightly strangled. The orifice was nicked and the opening was enlarged. The bowel was not quite dead, as it changed colour a little on releasing the strangulation. The patient died on the Monday; from the report given by the gentleman in charge of the case she seems to have quietly sunk away.

NEPHROLITHOTOMY.

The patient was a man aged fifty-five years. He was first seen in September, 1891. There was a history of some years of pain in the left side, which was worse after exertion. He was much troubled by a localised belt of sweating around the level of the left kidney. The patient looked like a sufferer from chronic Bright's disease. His urine was clear, with a slight amount of albumin. Microscopic examination revealed pus cells and crystals of oxalate of lime. He had never had any hæmaturia. The diagnosis was an oxalate stone in the left kidney. Lithia and other palliative treatment relieved him for a while. In 1894 he had a sharp attack of hæmaturia. Operation was always deprecated from the patient's general despondency—a bad subject for any surgical interference. In 1896 treatment seemed utterly useless and operation was to be risked. On August 6th, 1896, with the kind assistance of Mr. Morier and Mr. Weld, I cut down on the left kidney. The stone could not be felt with the fingers, but I struck it with a mounted needle. The

Digitized by Google

kidney was incised and the wound was plugged and enlarged with the finger and the stone grasped with cyst forceps and extracted by rotatory movement. Hæmorrhage was very free and the wound was plugged. For two weeks his condition was desperate. Some urinary infiltration of tissue of the back necessitated opening and draining the abscess. Mentally the patient was very queer till the seventeenth day, when he became completely himself again. The temperature was under 98° F. for the first three days after operation. A small oxalate of lime stone about 1 grain was passed *per urethram* eight days after the operation. The stone removed was a large mulberry calculus of oxalate of lime weighing 241 grains. (In this case I had the assistance of a trained nurse, who was most efficient and assiduous in her care of the patient.)

TRAUMATIC ABSCESS OF THE LIVER.

The patient, a middle-aged man, was kicked on the front of the left chest by a horse. The upper ribs were comminuted and pneumonia with effusion followed. He complained of great pain, too, over the liver. This was enlarged. The chest had to be aspirated three times, clear serum fluid being obtained each time. The enlargement of the liver becoming greater and more painful a teacupful of pus was drawn off by the aspirator; great relief followed. The pus did not reaccumulate and recovery was complete.

EPITHELIOMA.

The patient was a man, aged seventy-one years, with a very large epithelioma. He had been under the care of a woman quack. I had to remove more than half the lip. A new lip was made by bringing up the flaps from both sides of the centre of the chin and the gap was filled in by others taken from the skin of the neck below. Union was by first intention. The patient was most excitable. Over a pound of chloroform and nearly half a pound of ether were used at the operation and then anæsthesia was not complete. The epithelioma recurred twelve months later, but the patient was capsized from his cart and fortunately saved much suffering, his injuries proving fatal. Some smaller ones of the lip have been done with nothing noteworthy.

Epithelioma of the neck.—The position was unusual. The growth was freely excised; there has been no return so far and operation was performed three years since.

Epithelioma of the dorsum of the hand.—This was small; it was excised; there was no return. The patient was a married woman; her husband had a small growth on the lip removed. Both were done under cocaine.

LUXATIO ERECTA.

A man was going home in a cart drunk. The cart capsized, the horse in some way becoming freed. The patient was found under the cart with the right arm extended above the head. The head of the bone was in the axilla. I had to give chloroform single-handed and reduce with only a woman to help. The first attempt at reduction converted the dislocation into a subcoracoid and this was readily reduced by right-angled traction. Despite the length of time (as he was not discovered till morning) no injury occurred and the arm is as useful as ever. The rarity of this form of dislocation is the reason for noting it. I have seen numerous others with no special features. One had paralysis of the deltoid. The reduction in this case was wonderfully easy. The circumflex was injured in the fall.

EMPYEMATA.

1. The patient was a middle-aged medical man. When suffering from bronchial catarrh returning from a country journey one wet night his buggy was capsized turning a corner. His wife was with him instead of his groom, hence much more exertion and exposure were caused, no one being about at the time. Next day pneumonia set in. Both lungs were affected. Evidently there was fluid at the left base. Aspirating, I removed nearly a pint of laudable pus. Fortunately this did not reaccumulate. He has been practising for the eleven years following the use of the aspirator. All other empyemata have had to be treated by free incision with or without resection of the ribs. Those requiring removal of rib are referred to in gunshot cases and hydatid cases. In other cases there was nothing noticeable.

2. A boy, about ten years of age, was seen in consultation. He had recently suffered from acute pneumonia; he was going back—high temperature, sweating, &c., and signs of fluid in the right pleura. A large amount of pus was evacuated by the aspirator. Ten days later he was seen again and it was decided to try tapping once more. About the same amount of pus was removed. When asked to see him again two weeks later his distress was extreme. The right pleura was so full of fluid that the heart was displaced below the ribs. Chloroform was given, and with a fine trocar pus was allowed to flow slowly out. I was afraid that sudden relief from free incision would cause fatal syncope. Tension being thus reduced the chest was freely opened. Drainage-tubes were inserted. The boy made a good recovery. The cavity was sweet throughout. No washing-out was employed. Iodoform and salicylic wool dressings were used. Twelve months later the boy came under my care again with the same signs of fluid in the right side. A preliminary tapping showing pus, the chest was freely opened through the old incision. The boy made a good recovery and the last time I saw him he was actively engaged in playing football.

WOUND OF THE KNEE-JOINT.

A young man whilst engaged in barking missed his stroke and the tomahawk cut into the left knee-joint exposing the inner condyle of the femur. Synovial fluid was freely escaping. The wound was carefully cleaned with carbolic lotion and four stitches were inserted. The wound was dressed with iodoform and vaseline on lint with salicylic wool. A back splint was applied and the patient was kept in bed. On the fifth day the wound was dressed and the stitches were removed. Healing was by first intention. On the seventh day the patient was up and about and the knee was as good as ever.

COMPOUND FRACTURES.

Of these I shall only refer to three, the others having no special features.

1. *Comminuted fracture of the fibula, with compound dislocation of the ankle; fracture of the lower end of the tibia.*—The patient was a young woman. In attempting to mount her horse by herself she fell and sustained the above injuries. Reduction was easily effected under chloroform. Cellulitis followed, necessitating free incisions and drainage. More than six weeks after the injury there was no attempt at the formation of callus and it looked as if the amputation the friends thought inevitable at the first would have to be resorted to. Two weeks later there was evident repair going on. Then occurred an alarm of fire at night. The shock given to the patient caused plugging of the veins of the sound limb. This condition occasioned the greatest trouble both in the immediate and the remote stages of treatment. Several sequestrotomies were necessary, and one sequestrum removed consisted of the whole of the articular surface of the tibia. Bony union at the tibio-astragaloid joint occurred, but after nearly five months' confinement to bed the joints between the astragalus and scaphoid and os calcis and cuboid were quite freely moveable and no adhesions were formed. The patient can now walk many miles with ease; ordinarily there is no limp observable. The length of time in this case was greatly lengthened by the effect of the alarm of fire at night. One can scarcely think of any alarm likely to be more productive of harm than that of a fire to a person in bed with a fractured leg in Neville's splints.

2. A boy, aged about sixteen years, was run over by a dray with more than a ton of fireclay on it at the time. To make matters worse the horse stopped with the wheel on the limb, first passing over it and then backing on to it. There was a comminuted fracture of both bones in the centre with the rupture of a large muscular artery. Plugging had to be resorted to to arrest the hæmorrhage. Counter openings were necessary. The patient recovered with a most useful limb. Two or three small sequestra had to be removed subsequently. This would have been a good case for the use of Mr. Lane's screws, but they were not then known, from the oblique nature of the fractures.

3. *Compound fracture of the left innominate bone (iliac portion).*—A young man was thrown out of a cart on to some jagged rock. There was a large rent above Poupart's ligament and the anterior superior spine was broken off and the rim of the bone was generally comminuted. Many broken fragments were taken away. The skin wound was brought together with due attention to drainage. The peritoneum though exposed was fortunately not opened. The bladder being distended the urine was drawn off with a catheter and found to contain much blood. This gradually lessened. No albuminuria was left, the kidney completely recovering from its

Digitized by Google

injury. The youth was able to resume his ordinary employment.

HYDATIDS.

No one practising in Australia would escape getting cases of this, *the* peculiar disease of two such opposite countries as Australia and Iceland. The district which I have been living in is comparatively free from the scourge, but a few of the cases are worth passing attention.

1. The patient was a young girl, aged ten years. She had a tumour of the size of a small orange in the abdomen just above the bladder. The skin and parietes were freely moveable over it. The tumour itself was somewhat moveable. The tumour was cut down upon and the sac sewn to the edges of the abdominal wound. A drainage-tube was inserted. A mother cyst and many daughter cysts came away as the cavity closed. There was some trouble from retention of urine. The patient made a good recovery and has remained well since.

2. The patient was a woman, aged about thirty years. She had a large tumour of the abdomen, considered to be ovarian. This diagnosis was concurred in by such authorities as the late Dr. Davies Thomas, Dr. Gardner (now of Melbourne), Dr. Stirling, Dr. Way, and all who saw the case. Not having any conveniences at that time the patient was sent to Adelaide. Dr. Way operated. I was present at the time. The tumour turned out to be a huge hydatid. This case is mentioned to show how possible it is to make a mistake in the diagnosis of abdominal tumours. Recovery was good.

3. This patient was a child, aged ten years, with recurrent hydatid of the liver. More room being required, a portion of rib was excised. In this case the pleura was opened. The patient did very well for some days and then pneumothorax set in. There was a slight amount when seen one afternoon, but I did not anticipate the rapid way in which this increased, as it must have done from the symptoms described. The patient died during the night. This was one of my earliest cases, but in any future case I should certainly insert a tube into the pleural cavity if there were signs of a pneumothorax coming on in the course of convalescence where the pleura had been opened.

4. This patient was a young woman, aged thirty years. She had a history of cough for some time and pain in the right side. There was a crescentic area of dulness, convexity upwards, in the right axilla. The diagnosis was probably hydatid. A hypodermic needle drew off a little clear fluid; there were no hooklets. Ten days later the patient came again. She looked very sallow and wretched. The tumour was projecting from the epigastrium. Immediate operation was advised. Under chloroform I cut down and sewed the edges of the cyst to the abdominal incision. On free incision there was a large quantity of puriform fluid and collapsed hydatid cysts, very offensive. The cavity was washed out with Condy's fluid. Iodoform and vaseline dressing with pads absorbent salicylic wool. No rise of temperature occurred. Recovery was uneventful. The patient has since married and had a family. The fingers could reach to the axilla on the one side and feel the heart thumping against them on the other.

5. The patient was a German, aged sixty-four years, suffering from hydatid of the lung. Diagnosis was confirmed by the aspirator. For various reasons I had to transfer the patient to hospital in Adelaide. He was very averse to operation. A curious mistake was made in this case. Looking up Dr. Davies Thomas's mortality chart the death-rate from fifty to sixty years of age was read as higher than from sixty to seventy years of age. I sent the patient away in the firm conviction that he had a better chance of recovery at sixty-four years of age than he would have had if he were only fifty-four. I believe this materially helped the old man and I did not undeceive him. He recovered.

6. The patient was a married woman who had had several children. There was a history of hydatids coughed up some years since. She had a sharp attack of pneumonia of the right lung. She was under the care of my locum tenent, Dr. Moule. When I first saw the case I found signs of fluid at the base. There was no improvement after a short further course of treatment. The patient was sallow, perspiring freely when asleep—going down hill. She was five and a half months pregnant. Aspiration in the axilla only drew off a little blood. Below the angle of the scapula I struck thick pus. The patient was removed to Mr. Barker's. Chloroform was given, part of the rib was excised, and a large collapsed hydatid cyst presented. Recovery was most wonderfully rapid. She went to full time and was safely delivered of a healthy child.

7. The patient was a married woman with a large tumour of the liver. It was so irregular and the appearance was so bad that malignant disease was considered an equal possibility with hydatid. When seen a second time a small area of the size of a sixpence gave a peculiar thrill. Aspiration drew off a little typical hydatid fluid showing hooklets under the microscope. Two days later under A.C.E. I opened the abdomen and drew off a little fluid to reduce the tension of the distended part of the liver. The cyst was sutured to the abdominal wall and freely opened. The cavity was full of daughter cysts from the size of a pin's head to that of a goose's egg. Several bowlfuls of cysts were taken out by cyst forceps or irrigated away. Ten days after the operation bile began to be discharged and for some weeks enormous quantities of bile came away. As the cavity contracted this lessened and ceased. When last seen there was a small sinus; the patient was then suffering from an intercurrent attack of influenza. Recovery in this case was slow.

DIABETIC COMA; RECOVERY BY ADMINISTERING OXYGEN GAS.

A very interesting case, though hardly a surgical one, was that of an elderly woman seen for the first time one evening in a comatose state. Fortunately, some urine had been left in the chamber and this contained a large quantity of sugar. There being no improvement after some few hours I thought I would try oxygen gas. Her neighbour was the headmaster of the Government school, who was, I knew, studying chemistry. From him I got a flask and some glass tubing and rigged up an arrangement by which I generated O_2 from chlorate of potash and black oxide of manganese, led it through a wash-bottle and brought it to the patient's face by indiarubber tubing. After a while consciousness began to return. Recovery for the time was complete, the patient dying some eight months later from other diabetic complications.

NÆVI.

The patient was a boy, aged two or three years, with a large venous nævus of the right orbit. Ligature was thought to be the most suitable means of treatment and the growth was tied under chloroform by a triple interlocking thread. The thickness of the growth necessitated a second ligature of the stump. The whole then sloughed away. The line of scar took the fold of the lower lid so that absolutely no scar was to be seen except on very close inspection.

Another patient had a very large one over the upper part of the sternum. Ligature resulted most favourably in this case too. Capillary nævi have been treated by nitric acid and ethylate of soda in the usual way.

SEBACEOUS CYSTS OF THE RIGHT LABIUM MAJUS.

Cysts of this kind in this situation are so uncommon that I venture to record the case. A young woman, aged eighteen years, was brought by her mother. Examination revealed two separate cysts in the right labium. They were removed under chloroform and contained the usual contents of sebaceous cysts. Recovery was uneventful.

I must not unduly prolong this already lengthy communication with any general conclusions. The cases recorded may serve to show to some who are impressed with all the assistance and appliances of the modern operating room that much, very much, can be done by a careful attention to detail with very primitive help in the shape of appliances and nursing and with a minimum of qualified assistance. I cannot conclude without a few words in favour of the old-fashioned poultice. In ordinary surgical work undoubtedly there is but little occasion for it. We do not expect nor do we often see pus in operations conducted with proper regard to asepsis and antisepsis. On the other hand, we are called to cases where nothing is so soothing or so cleansing as a well-made and properly-applied poultice. Under its soothing influence the restless patient often drops off to sleep. The chief argument against it is that it is a rapid breeder of bacilli, bacteria, *et hoc genus omne*. This is the true reason of its value. Why does it cleanse a sloughing ulcer or a foul-smelling abscess cavity? Because of its affinity for germs. They transfer themselves from the less attractive body nidus to the warm linseed and meet the fate worthy of their ficklenes in the devouring fire which is, of course, the only safe depository for a soiled poultice or dressings.

REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR THE YEAR 1896.[1]

FIRST NOTICE.

THE fact that this voluminous report relates to occurrences making up the medical history of India during 1896 is likely to exercise a somewhat deterrent effect upon the reader in 1898. Looking, however, to the large mass of information which is embodied in it and to the fact that this information has to be collected from all parts of a vast country like India, that it has then to be arranged, compiled, and edited, and that as an official record of the Government these reports have to be accurate and reliable, we presume the delay in their publication is unavoidable; but it naturally takes away any keenness of edge in the interest and appetite of the reader. These reports are, however, by no means a bare record of facts and figures and tabular statements. They are accompanied by a text and commentary of a learned and very useful kind, in which a good deal of reference is made to, and a brief analysis is given of, contemporary medical literature, both foreign and English. It is mainly owing to this fact—apart from the vital statistics and official record of the medical events set forth, which make the reports valuable to the statesman as well as to the medical statist—that these volumes are of interest and practical utility to the professional reader and epidemiologist. A new and excellent map of India is prefixed to the present report, showing a revision of the boundaries of the geographical groups. Section I. deals with the meteorology of the year, which need not detain us long. But meteorology probably holds a much more important relation to the health and well-being of the people of India than it does elsewhere. The regular periodicity of the seasons and, it may even be said, the periodicity stamped upon the character of the diseases, are very notable features of that climate. India is much more dependent than most countries on its rainfall. If there is no monsoon it means famine, and any deficiency even in this respect at once affects the price of food; on the other hand, if the monsoon be excessive it either leads to waterlogging of the soil or to a rise of the level of the subsoil water, with the upward movement and escape of malarial agents (the plasmodium malariæ) from the soil and the concomitant outbreaks or increased prevalence of ague and malarial fevers. The natives of India are for the most part extremely poor; bad crops, with increased dearness of food as a consequence, lead to starvation which greatly increases the predisposition to disease and diminishes the chances of recovery in those attacked. All this, however, is more or less obvious.

Section II. deals with the European army of India, and we may say *en passant* that the reader will find that a comparison between this section and that on the native army of India is worth instituting, because it serves to bring out some striking differences in the nature of the diseases to which Europeans and natives respectively are most liable. In 1896, out of a strength of 70,584 European troops there were 1387 admissions to hospital, 94 constantly sick, 14·84 deaths, and an invaliding of 28 per 1000 of strength respectively, the total loss amounting to 43 per 1000, which is a somewhat higher ratio than for previous years. The chief causes of admission were venereal diseases and ague. The former caused 37 per cent. of the total sickness and ague 17 per cent. The chief causes of death were enteric fever and hepatic abscess, but the mortality from ague, dysentery, diarrhœa, hepatic abscess, and enteric fever was lessened in 1896. Still enteric fever caused nearly 43 per cent. of the total deaths and hepatic abscess 8 per cent. The chief causes of invaliding were syphilis and gonorrhœa, debility, tubercle of the lungs, and malarial fever. Table I. of the report gives the ratios of the four commands placed side by side. Bengal has, we are told, the highest mortality from cholera, enteric fever, ague, dysentery, and hepatic abscess; the Punjab the highest from remittent fever, heat-stroke and pneumonia, and the lowest from cholera, small-pox and dysentery; Madras, the lowest from enteric fever, heat-stroke and pneumonia, and Bombay the highest from small-pox. The percentage of enteric fever in the total deaths was greatest in the Punjab, and the percentage of hepatic abscess in Bengal. The total death-rate of Bengal, which was the highest, was not far from being double that of Madras, which was the lowest. Burma, in 1896 was distinguished by the prevalence of influenza, simple continued fever, and hepatitis. Allahabad had a high death-rate attributable to an increase of enteric fever. Among the British infantry the 1st Norfolk Regiment at this station had the highest mortality; it had 93 admissions and 32 deaths from enteric fever. The first epidemic year of influenza in India was 1890, and a table is given of the fluctuations of the disease since that year. The amount of cholera in 1896 among the troops was higher than in 1895, but the ratios were lower than those of the decennium and there was no marked prevalence of the disease; the death-rate from cholera in 1896 was 0·89, as against 0·43 per 1000 in the previous year. The admission-rate for small-pox was nearly six times, and the death-rate nearly five times, as great as in 1895. There were 122 cases of small-pox with 10 deaths in 1896, as against 19 cases and 2 deaths in 1895. The comments and remarks on this disease in relation to vaccination and the importance of successful revaccination are interesting, but these require to be read in detail. As regards fevers it seems to be established that so-called Malta fever occurs in India. The blood-serum of some soldiers invalided to Netley from some Indian stations was found to react specifically with the micrococcus melitensis. By the use of the method of serum diagnosis it has been shown that the true cause of Malta fever is this micrococcus, and there is now, as we have said, reason to believe that the same form of fever prevails in India. The report then proceeds to the discussion of enteric fever—that scourge of the European army in India and the scourge, indeed, of all armies in the field, as among the American troops in Cuba and the British in the Soudan and Egypt for example. We must, however, for the present defer the further consideration of this report.

THE OUTBREAK OF TYPHOID FEVER IN BELFAST.

STATISTICS, as reported to a meeting of the Public Health Committee on Sept. 15th, for the week ending Sept. 10th, show that the death-rate from all causes in Belfast was 27·9 and from the principal zymotic diseases 10·8 per 1000. There had been notified during the same period 378 cases of infectious disease as follows: 10 of diphtheria, 6 of erysipelas, 12 of scarlet fever, 1 of typhus fever, 270 of typhoid fever, and 79 of simple or continued fever. In the face of such a high general death-rate and of such an extraordinary mortality from zymotic diseases the citizens of Belfast have been astounded at the action of the Public Health Committee. Instead of boldly facing these appalling facts laid before them by their own medical officer of health they take refuge in a most absurd piece of special pleading. Firstly, they allege that in certain cases there has been an abuse of the Notification of Infectious Diseases Act, owing to the fact that a second medical practitioner has for some reason or other been called in to consult about, or to take charge of, patients whose cases have already been notified, and he in due course also notifies the fact of which the authorities are already aware and thus cases are duplicated. This is possible, but does anyone for a moment believe that such twice-reported cases are so numerous as really to vitiate the general and authoritative statistics? and does not the very fact of such an excuse being put forward show that in the Public Health Office there is no really competent classification of entries of cases reported, otherwise such slips or mistakes would be at once made right? Secondly, instead of taking the proper and effective course of doing away altogether with pigstyes in the city it is coolly proposed to recommend the City Council to amend their by-laws for the regulation of piggeries so as to render compulsory the registration of the establishment of "pig-culture," in order that the officers of the health department may have the same convenience of inspection and control as they have over cowsheds and dairies. Thirdly, the public are told that "numerous

Digitized by Google

complaints were received as to the offensive smells arising from sewer ventilators, the evident impression being that these gratings were expected to emit vapour with a fragrant bouquet and that the Public Health Committee were responsible for the disappointment." Such sarcasm is altogether out of place. Every one knows that sewer-air must find an outlet somewhere and that ventilating shafts would be an improvement on the present street traps, but what is wrong with these Belfast drains that they require in places constantly to be cleaned out and that after heavy rains it is noticed that the health of the population shows a general improvement? Surely it is evident that they allow a great accumulation of filth which is not properly removed. Public opinion is awakening in Belfast; the articles of the Special Sanitary Commissioner in THE LANCET are being reprinted in the public press of the city and are having a most educating effect; and as an evidence of the present tone of public opinion the following from a Belfast morning paper of Sept. 16th may be quoted:—

The Public Health Committee will have to go far beyond ingenious suggestions that some typhoid cases are reported twice, recommendations for the registration of pigstyes, or sarcastic hits at various complainants. Few will have the hardihood to deny that the health of the city has been most unsatisfactory or that the citizens have in great degree been reaping to their sorrow what in the past successive town or city councils, improvement committees, or public health committees have sown. It is certainly no pleasure to us to have to repeat this—quite the reverse. We should be sincerely sorry to sound an unnecessary alarmist note or to give countenance to any exaggeration. Nothing could be further from our wishes than any attempt to "blacken the reputation of the city," as an eminent corporator put it at a recent meeting of the City Council. But the methods of the ostrich are, to say the least, of very doubtful wisdom. The reputation of the city is what it was inevitably made by those who in the past permitted the jerry-builder to work his wicked will, who winked at the erection of houses upon vile, filth-sodden, filling-up stuff—of houses to the number of so many thousands without back passages, and with the disgusting and dangerous system of dry privies. The sanitary sins of the past have been finding us out, but unhappily the innocent suffer for the guilty. It is the duty of the City Council and the committees concerned, instead of attempting to minimise the gravity of the situation, to see that these sins and their evil consequences are not perpetuated. They will have their hands more than full inside the city itself, while they will have to very seriously consider the system under which the lough at our doors, so to speak, has been turned from a picturesque expanse of water into "a stinking cesspool." Beginning with themselves, they will have to deal with a more than Draconian severity with all offenders against sanitary laws, making the interests of the public health, not those of any individual, the sole basis of their action. And they will have to see that while the city is so far as possible cleared of the grossest dangers its filth is not merely swept over the threshold to lie and fester and breed disease on the shores of the lough. This may seem indefinite, but the evils have been often defined and the remedies and palliatives often indicated. They will cost money and labour, but the price is nothing in proportion to the good to be gained—improved health for the citizens and a decent sanitary reputation for the city which will not be liable to suffer at every breath of plain and honest criticism.

The City Corporation will meet on Oct. 1st, when it is expected there will be a very lively discussion on the typhoid fever epidemic. It would be as well if the members of that body who feel that the Public Health Department is totally incompetent to deal with the present deplorable sanitary condition of Belfast were to suggest calling in an extern authority such as Dr. Russell, medical officer of health of Glasgow, Sir Richard Thorne, medical officer of the English Local Government Board, or Dr. Niven, medical officer of health of Manchester, to advise what is best to be done so as to remedy the present sadly disgraceful sanitary state of that city.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Report upon the Sanitary Conditions of the Urban District of Alnwick and upon Housing of the Working Classes therein, by Dr. G. S. BUCHANAN.[1]—The County Council of Northumberland in December of last year made representations to the Local Government Board as to certain unwholesome conditions which had been discovered in Alnwick by Dr. Hembrough, the county medical officer of health. The local medical officer of health shared Dr. Hembrough's views, but the district council took no adequate action. The Local Government Board therefore sent down Dr. G. S. Buchanan, who has recently, through this Board, presented the public with a very detailed account of the shortcomings, *quâ* sanitation, of the Alnwick District Council. As long ago as 1852–54 Alnwick was sewered, but in spite of this no diminution in the general mortality rate took place and the phthisis rate remained inordinately high. This fact seems to have disheartened the sanitary authority, and Dr. Buchanan reports that their later administration has been "conspicuously lax." It would appear, indeed, that the local authority have throughout either been devoid of backbone or, what really comes to the same thing, have had a backbone consisting of those interested in insanitary property who neglected to take proper action when unwholesome conditions were brought to their notice. The late Mr. Spear, who inspected this district in 1885, clearly diagnosed the condition from which the sanitary authority suffered when he wrote: "Wherever individual interests have to be opposed, or seemingly opposed, sanitary administration has been paralysed." Evidently, too, Dr. Buchanan found the same conditions obtaining at the date of his recent visit, and in spite of a sewerage system, a public water-supply, and an isolation hospital we find that the poorer classes are shamefully housed and that a large proportion of the dwellings of the town are to be found huddled together on small areas at the back of the main thoroughfares. Dr. Buchanan paints a graphic picture of the manner in which this overcrowding of houses upon areas was gradually brought about. He tells us how the long strip of garden behind the house facing the main thoroughfares was covered by the operations of the jerry builder of former days and how through the ground floor of the front house the passage was knocked which now gives entrance to the alley or court in which are the overcrowded and dilapidated dwellings which he condemns so strongly. Time after time has the attention of the sanitary authority been drawn by the medical officer of health to this crowding of houses upon areas, and as often has the appeal for remedy been passed over, if not in silence at least without adequate action. As instances of extreme overcrowding Dr. Buchanan mentions a single room of barely 1000 cubic feet capacity inhabited by a family of eight, and a six-roomed house sub-let in tenements which was said to be occupied by thirty-one persons. It is, however, some consolation to find towards the end of the report before us that in January last a "Town Improvement Committee" was appointed who really seem bent on putting an end to the state of affairs revealed in turn by the late Sir George Buchanan, by the late Mr. Spear, by successive medical officers of health of Alnwick, by Dr. Hembrough, and now, let us hope finally, by Sir George Buchanan's son. Many of the dwellings here in question are, it appears, beyond remedy and comprehensive action under the Housing of the Working Classes Act seems the only solution of the difficulty. Dr. Buchanan has, however, mapped out the "insanitary areas" for the district council and told them of the death-rates, &c. He has, indeed, done everything but find the money, and even in this direction we may be sure that he will influence the Local Government Board to deal kindly with the authority in the matter of loans.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6504 births and 5165 deaths were registered during the week ending Sept. 17th. The annual rate of mortality in these towns, which had increased in the nine preceding weeks from 14·7 to 24·6 per 1000, declined last week to 24·0. In London the rate was 21·2 per 1000, while it averaged 25·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 15·1 in West Ham, 15·8 in Swansea, 16·3 in Croydon, and 16·5 in Portsmouth; the highest rates were 34·8 in Salford, 37·0 in Bolton, 37·2 in Gateshead, and 40·6 in Sunderland. The 5165 deaths in these towns included 1545 which were referred to the principal zymotic diseases, against 1646 and 1578 in the two preceding weeks; of these, 1315 resulted from diarrhœa, 70 from diphtheria, 67 from whooping-cough, 43 from "fever" (principally enteric), 28 from measles, 22 from scarlet fever, and not one from small-pox. The lowest

Digitized by Google

death-rates from these diseases were recorded in Portsmouth, Plymouth, Swansea, and Birkenhead; and the highest rates in Norwich, Bolton, Salford, Sunderland, and Gateshead. The greatest mortality from measles occurred in Plymouth; from scarlet fever in Huddersfield; from whooping-cough in Preston, Halifax, and Cardiff; and from diarrhœa in Wolverhampton, Norwich, Salford, Bolton, Gateshead, and Sunderland. The 70 deaths from diphtheria included 29 in London, 10 in Leeds, 6 in West Ham, 5 in Manchester, 4 in Swansea, and 3 in Liverpool. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and only 2 small-pox patients were under treatment in the Metropolitan Asylum Hospitals on Saturday last, Sept. 17th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 2319, against 2178, 2240, and 2300 on the three preceding Saturdays; 242 new cases were admitted during last week, against 182, 238, and 273 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 127 and 130 in the two preceding weeks, further rose to 135 last week, but were 21 below the corrected average. The causes of 54, or 1·1 per cent. of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Newcastle-upon-Tyne, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the four preceding weeks from 18·1 to 23·0 per 1000, declined again to 18·8 during the week ending Sept. 17th, but was 5·2 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·4 in Edinburgh and 17·0 in Greenock to 19·8 in Glasgow and in Leith, and 20·4 in Perth. The 567 deaths in these towns included 110 which were referred to diarrhœa, 21 to whooping-cough, 9 to "fever," 9 to measles, 5 to diphtheria. and 3 to scarlet fever. In all, 157 deaths resulted from these principal zymotic diseases against 124 and 140 in the two preceding weeks. These 157 deaths were equal to an annual rate of 5·2 per 1000, which was 2·0 per cent. below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 81 and 92 in the two preceding weeks, further rose to 110 last week, of which 49 occurred in Glasgow, 19 in Dundee, and 15 in Edinburgh, The 21 deaths from whooping-cough were within one of the number in the preceding week, and included 7 in Glasgow, 6 in Edinburgh, and 6 in Aberdeen. The fatal cases of measles, which had been 6 and 9 in the two preceding weeks, were again 9 last week, of which 6 occurred in Edinburgh. The 9 deaths referred to different forms of "fever" corresponded with the number in each of the four preceding weeks and included 6 in Glasgow, where 3 of the 5 fatal cases of diphtheria were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 72 and 100 in the two preceding weeks, declined again to 68 last week, and were 28 below the number in the corresponding period of last year. The causes of 22, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 21·8 to 30·7 per 1000 in the four preceding weeks, declined again to 27·1 during the week ending Sept. 17th. During the past four weeks the rate of mortality in the city has averaged 27·0 per 1000, the rate during the same period being 22·0 in London and 18·7 in Edinburgh. The 182 deaths registered in Dublin during the week under notice showed a decline of 24 from the number in the preceding week, and included 35 which were referred to the principal zymotic diseases, against 39 and 54 in the two preceding weeks; of these, 26 resulted from diarrhœa, 4 from whooping-cough, 3 from "fever," 1 from measles, 1 from diphtheria, and not one either from small-pox or scarlet-fever. These 35 deaths were equal to an annual rate of 5·2 per 1000, the zymotic death-rate during the same period being 6·3 in London and 5·3 in Edinburgh. The fatal cases of diarrhœa, which had increased from 4 to 38 in the eight preceding weeks, declined to 26 last week. The 4 deaths from whooping-cough were within 2 of the number recorded in the preceding week. The deaths referred to different forms of "fever," which had been 1 and 5 in the two preceding weeks, declined to 3 last week. The mortality from measles corresponded with that recorded in the preceding week. The 182 deaths in Dublin last week included 52 of infants under one year of age, and 40 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Seven inquest cases and 7 deaths from violence were registered; and 63, or rather more than a third, of the deaths occurred in public institutions. The causes of 12, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

STAFF-SURGEON JOHN SPEARE LAMBERT has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet. The under-mentioned Surgeons have been promoted to the rank of Staff-Surgeon in Her Majesty's Fleet:—Alfred Ernest Weightman, James Walter Octavius Underhill, Charles Hazlitt Upham, Frederick James Burns, Daniel Joseph Patrick McNabb, Charles Strickland, James Mead France, John Menary, Walter Godfrey Axford, George Thomas Broatch, William Bett, Frederick Augustus Brice, John Walter Slaughter, and George Henry Foott.

The following appointments are notified:—Staff-Surgeons: R. M. Young to the *Diadem;* W. Bett to the *Centurion*, for service at Wei-Hai-Wei; C. Strickland to the *Medea;* and J. M. France to the *Briton.* Surgeons: Edward D. J. O'Malley to the *Victory*, additional, for disposal; W. E. Marshall to the *Melita*, additional; N. L. Richards to the *Diadem;* J. C. Durston to the *Wildfire;* and J. W. Bird to the *Impregnable.*

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. H. Macnamara to be Colonel, vice C. F. Pollock, retired. Surgeon-Captain Stacey, Army Medical Reserve, assumes the duties of assistant to the medical officer in charge at Norwich. Major Davidson takes over the medical charge of the Female Hospital, officers, women, and children, at Colchester. Captain Profeit has been granted leave, with permission to go to France and Switzerland. Major Beevor has been appointed Surgeon-Major, Coldstream Guards. The authorities appear to have had to overcome a difficulty in announcing this appointment, for this officer is a major of the Royal Army Medical Corps, but not a major of the Coldstream Guards, which is a purely regimental appointment and title, but he is nevertheless acting as a medical officer of that regiment, so he is called by his rank and title of Major R.A.M.C. and appointed to the post of Surgeon-Major in the Coldstreams.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions in the Indian Medical Service made by the Government of India:—To be Colonel: Brigade-Surgeon-Lieutenant-Colonel William Edward Johnson, Madras Establishment. The Queen has also approved of the retirement from the Service of the under-mentioned officers: *Bengal Establishment:* Colonel Sir George Thomson, K.C.B., Lieutenant-Colonel Joseph O'Brien, and Lieutenant-Colonel Kali Pada Gupta. *Bombay Establishment:* Major Alexander Frederick Ferguson.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major F. F. Moore, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers. Surgeon-Captain D. Lennox to be Surgeon-Major. Surgeon-Captain R. P. MacKenzie, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 1st Cumberland: Surgeon-Lieutenant R. L. Clark to be Surgeon-Captain. *Rifle:* 2nd (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Lieutenant H. A. Rudyard to be Surgeon-Captain. 16th Middlesex (London Irish): Surgeon-Lieutenant E. W. St. V. Ryan to be Surgeon-Captain. 1st (Cumberland)

Digitized by Google

Volunteer Battalion the Border Regiment: Samuel Braithwaite is re-appointed Surgeon-Lieutenant. 1st Volunteer Battalion the Prince of Wales's Volunteers (South Lancashire Regiment): Captain John Nesbitt Patterson resigns his commission, and is appointed Surgeon-Lieutenant. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant J. Taylor to be Surgeon-Captain.

THE INDIAN MEDICAL SERVICE.

The *Pioneer Mail* of Sept. 2nd announces that a telegram received in Simla states officially that the name of the Indian Medical Service is to remain unchanged. There will thus be no Royal Indian Medical Corps, though the members of the service receive military titles in common with their *confrères* in the now extinct Army Medical Staff. It is premature at present to decide whether this decision will prove satisfactory or not to officers of the Indian Medical Service. That service has fine traditions and a deservedly high reputation and its members may on that account be desirous of retaining its name. On the whole it seems to us, however, that it would have been preferable at the present time to have changed its title to that of the Royal Indian Medical Corps.

THE LATE SPANISH-AMERICAN WAR.

The President of the United States has decided that an investigation shall be made by a committee into the conduct of the War Department during the late hostilities with Spain. Some of the main objects in view are to examine into the conduct of the commissary quartermaster and the medical bureau of the War Department and to ascertain the extent, causes, and treatment of the sickness which prevailed in the field and camps during the late war. The estimated total of those who died from disease is given as 2086, while the estimated total of those attacked by disease was excessive. During the war 279 men were, it is alleged, killed and 1423 wounded.

THE TROOPS IN THE KHYBER PASS.

The health of the troops in the Khyber has been already much benefited by the approach of cooler weather and it is still improving. There is a growing belief in official circles that the Khyber will be taken over by the Government of India.

THE LATE FRONTIER WAR IN INDIA.

In consequence of services rendered during the recent frontier operations a number of promotions in the Subordinate Medical Department of India have taken place.

Captain Robert Frazer Standage, I.M.S., who did such excellent work in the engagement with the Soudanese mutineers near Mruli on April 26th, has been brought to the notice of the authorities. He was appointed Surgeon-Lieutenant in 1895.

Lieutenant Thomas Henry Matthews Clarke, R.A.M.C., who, we regret to learn, was wounded in the recent disturbances in Crete, is twenty-five years of age and was appointed Surgeon-Lieutenant in 1897.

Captain G. T. Rawnsley, R.A.M.C., has been appointed an Esquire of the Order of the Hospital of St. John of Jerusalem in England.

CORPORATE AND MEDICAL REFORM ASSOCIATION AT STAMFORD.—A meeting of the profession of Stamford and the neighbourhood, convened by the medical staff, was held at the Rutland, Lincoln and Stamford Infirmary on Sept. 15th to hear an address by Mr. R. B. Anderson. Mr. William Newman took the chair. Mr. Anderson traced the policy of the association to resolutions of the medical members of the Civil Rights Defence Committee affirming the obligation of the General Medical Council and qualifying corporations to make good the rights by conferring and guaranteeing which (respectively) they exist, an obligation which he described as fully sustained in a series of articles in THE LANCET in 1896. The chairman contrasted the position and influence of the medical profession in the State with the far greater influence and more advantageous position of the sister profession of the law, and after some questions and discussion resolutions were adopted *nem. con.* supporting the principles and policy of the Corporate and Medical Reform Association and appointing a committee to coöperate in promoting its objects in the locality. With votes of thanks to Mr. Anderson and to the chairman for presiding the meeting terminated.

Correspondence.

"Audi alteram partem."

"THE PLAISTOW MATERNITY CHARITY."

To the Editors of THE LANCET.

SIRS,—We are directed by the Executive Council of the East Suburban Medical Protection Society to reply to Mr. Arthur Pritchard's letter in your issue of Sept. 10th. Although not directly challenged by him, and although we are in official correspondence with the committee of the Plaistow Maternity Charity, the council feel that we ought not to leave unrebuked his somewhat ungenerous estimate of our position and motives. If our position had not an element of dignity and our motives of altruism our views would not have found a place in the columns of THE LANCET; while, on the other hand, we should be unworthy members of the healing profession if we refused our advice and assistance to the benevolent in their attempt to provide gratuitous nursing for the sick poor.

Unfortunately this Plaistow Maternity Charity has hitherto been administered by amateurs and certain errors have in consequence arisen. We are immediately concerned with the three following departments of the work: 1 The midwives' practice. 2. The district nursing. 3. The training of nurses. Now, Mr. Pritchard in his letter to you treats these *en masse*, whereas it is essential that they should be treated separately; for the one is in direct opposition to qualified practice and the other two depend for their success upon the coöperation of medical men. 1. It is in the midwives' practice alone that fees are taken; it is the midwives' practice that is pauperising the district, for even the well-to-do have a colourable excuse or, according to Mr. Pritchard, a "right" to employ the midwives; and it is in the midwifery cases that the nurses are taught to do without medical supervision. Now, we are at issue with Mr. Pritchard on this point. He claims "the right of the patient to choose between a midwife and a local medical man." We will admit the right of an individual to risk his life for a sufficient reason, but surely it is no part of the duty of a philanthropic body to encourage the poor and ignorant in running such a risk, least of all to save their pride or their pockets. It cannot be denied that it is safer to have a qualified medical man in attendance upon a parturient woman than a certificated midwife. Yet the Plaistow Maternity Charity has deprived the Poor-law medical officers of the greater part of their pauper midwifery practice and actually appeals to the board of guardians for support on the plea that it effects a saving in the rates. Mr. Pritchard also says that because the 10*s.* fee only covers the cost to the institution of attendance on a maternity case it is a misrepresentation to say that the patient gets any benefit out of the charity. Is it not generally considered a benefit to obtain an article at cost price? Does not the paying patient take one nurse away from her legitimate work among the poor? We have a right to expect more knowledge of economic laws from Mr. Pritchard. It is manifest abuse to buy or to sell, at whatever figure, that which is dedicated by the benevolent to the uses of the poor. Subscriptions to a charity do not entitle a man to use the charity: there is only one ground of claim—poverty. The fee is said to have been "raised from 5*s.* to 10*s.* with a view to meeting certain objections advanced by this medical protection society." This is a good example of the way the house committee deals with professional criticism. We objected to fees being charged in maternity cases, thereupon the committee raised the fee. Naturally we considered this a challenge, not a concession. 2. The district nursing is handicapped by the maternity department, for the latter makes the doctors loath to call in Sister Katherine's nurses and accustoms the nurses to disregard the doctors, in spite of rules and regulations to the contrary. As to the "few trifling cases" which Mr. Pritchard says the nurses have attended without a doctor we will only state here that the evidence in our possession shows that in some at any rate of these cases the supervision of a medical man would have been of advantage to the patients. 3. To criticise the system of training prevalent in this institution is beyond the scope of this letter, but those of your

Digitized by Google

readers who have not seen its annual report for 1897 will be interested to learn that it is described therein as "a nursing school for all England."

The west-end philanthropist, though far too polite to say so, appears to think the east-end doctor neither a man of education nor a man of honour. He does not ask us for help or advice in conducting a most difficult and essentially professional enterprise; he does not deign to employ logical arguments to meet our objections; and, finally, as instance Mr. Pritchard, he is surprised and a little hurt because we are not content to hold our tongues and squeeze what indirect advantage we can from an institution supported by charity. While we are willing to accept the larger share of blame for this as due to our supineness in the past we insist that concession should not be wholly on our side and hope that in the face of recent difficulties and failures the house committee of the Plaistow Maternity Charity will adopt the two initial reforms we are suggesting—viz.: (*a*) abolition of all fees in maternity cases and (*b*) adequate representation of the local medical profession upon the committee of management.

We are, Sirs, yours faithfully,
R. BUKSH.
FRAS. E. BROMLEY.
J. HEFFERNAN.
P. NAPIER JONES.

Plaistow, E., Sept. 20th, 1898.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 17th you publish a report on the Abuse of Nursing Charities from your Special Commissioner which I cannot allow to pass without a brief comment on some of the facts therein shown. Your Commissioner reports: "Thus a general practitioner related to me that a nurse from the Plaistow Maternity Charity came to him and asked for his assistance in a case of retained placenta. The nurse said that she had been to several other medical men and they had all refused to have anything to do with the case. My informant likewise refused. He argued that medical men should not be thus utilised at the last moment to get a nurse out of a scrape."

No doubt this gentleman would attend a case of chronic drunkenness, where delirium tremens or other complications had supervened, though not called in till the very last moment, but he would not attend a poor woman in imminent danger on the supervention of a complication which could not be foreseen and in what may quite well have been up to that point an ordinary case of labour. Would he have refused to attend the woman if when he had got to the house he had for the first time discovered that a midwife was in attendance? and would it have made a difference to him whether that midwife was trained or untrained? From your Commissioner's report it would appear that he would have assisted the untrained woman's patient but not the trained woman's. And yet the object of the training is, to a great extent, to teach the nurse to know when to send for medical assistance, and, indeed, trained midwives are bound to do so. It is evident that much valuable time was wasted in the case while the nurse, who, after all, could only act as the messenger of the patient, was trying to get qualified attendance for her patient.

May I point out some of the logical consequences of such an abuse of medical position? 1. The nurse will in the future not trouble to call in a qualified practitioner if at all doubtful of his opinions, but if the case be urgent will proceed to operate for herself. The first rebuff, at all events, will appear to her to justify her in thus acting. In a more difficult case she will send for a medical man whom she knows is disposed to help her patients, and this will involve the introduction of fresh medical competition into the district. 2. The nurse will be, to a certain degree, compelled to get more highly trained than she is at present and this will not be too favourable to the pecuniary interests of the trades unionists. 3. Medical men who attend people in such emergencies will be boycotted by their (trades-union) neighbours and they will then be between the coroner's warrant and their neighbours' ill-will. 4. The public will not patronise men whom they know to be bound by rules which disregard everything but the pecuniary necessities of trade. Trades unionists cannot stop from obstructing all measures which interfere with the extension of their trade; logically, they are bound to go on. Unfortunately for the pecuniary interests of the medical profession, its duty is to stop the spread of that very condition which fills its pockets. If once we sanction such proceedings as those I have quoted—forced, perhaps, to do so under penalties—farewell to our honour as medical men.

In view of the fact that the parish medical officer is bound to attend under such circumstances it is hopeless to try to prevent the patients of midwives from receiving qualified medical assistance when their condition requires it, and if what is evidently a local agreement to this effect were to become at all general, general practitioners would soon be left to enjoy their own society at their own cost. There is a right and a wrong way of filling one's pocket. These gentlemen have started on the wrong path. Let us hope that they will stop and that their example may prove a warning to others. I am, Sirs, yours faithfully,

F. R. HUMPHREYS.

Fellows-road, South Hampstead, N.W., Sept. 19th, 1898.

"TUBERCULOSIS AND THE MILK-SUPPLY."

To the Editors of THE LANCET.

SIRS,—One of the statements made in the lecture on Tuberculosis and the Milk-supply, published in THE LANCET of Sept. 17th, is slightly inaccurate. It was based on information given to me just before the lecture, but a more detailed examination of the cases show that one of the cow-sheds had not been examined, and in two cases instead of one the veterinary surgeon failed to see evidences of disease of the udder. Page 736, second column, line 10 from the bottom, instead of "Dr. Rivers informs me," read "Dr. Niven informs me that after receiving the results of my examinations the Sanitary Committee asked Mr. King to visit the cow-sheds from which milk had come which had been found tuberculous. Mr. King found that in fourteen out of the sixteen byres he examined there were cows with diseased udders," &c. I am, Sirs, yours faithfully,

Manchester, Sept. 17th, 1898. SHERIDAN DELÉPINE.

SUNSTROKE OR DELIRIUM TREMENS.

To the Editors of THE LANCET.

SIRS,—That sunstroke should be followed by mental derangement is *a priori* probable, and if there have been any authenticated cases of such a sequence during the heat wave it would be very interesting to have them recorded. Sunstroke has for long been recognised as one of the antecedents of insanity and a large number of cases of the latter malady come under care with a history of the former, but upon strict investigation it is almost constantly found that the symptoms of the "sunstroke," while they do not agree with the classical course of that malady, bear a striking resemblance to those of delirium tremens.

I am, Sirs, yours faithfully,

Catford, S.E., Sept. 16th, 1898. CHAS. MERCIER.

ANILINE COAL-TAR DYES.

To the Editors of THE LANCET.

SIRS,—The interesting and important case of death from effects of poison introduced into the skin by the use of stockings dyed with some poisonous dye referred to in an annotation in THE LANCET of Sept. 10th should draw professional and public attention to the serious results which often occur to persons who wear coloured hose, &c. Some years ago I drew attention—in the International Health Exhibition in London, 1884—to the evil effects of wearing hose dyed with aniline coal-tar dyes, showing the stuffs so dyed which I had collected from cases in which the patients had consulted me about certain eruptions caused thereby, and I went thoroughly into the matter with the assistance of my friend Dr. Hind, then medical officer of health to Manchester, and we found not only the aniline dyes such as rose aniline, rocceline, and azo-benzole red were very injurious to the skin if absorbed, producing violent inflammation and dermatitis, but that the fixing products, such as bichromate of potash, arsenic, &c., also produced the same very irritant effects. The septicæmia caused in the above instance at Hull might have been caused by the dye. I may mention two or three

Digitized by Google

instances which have quite recently come under my notice 1. A lady, the wife of a medical man, called me to see her She was suffering from great inflammation and an angry wound of the leg followed by acute dermatitis of the whole body, with rise in temperature, after wearing some new stockings from which the dye had become absorbed. 2. Another lady consulted me with almost precisely the same eruptions, having absorbed the dye from a black stocking after an abrasion to the skin. 3. A lady consulted me with a violent eruption all over the shoulders and arms after when heated wearing a red dressing-gown—a portion of which I enclose—no doubt dyed with aniline dye.

The subject is by no means new, but it seems to me a matter of much professional and public interest.

I am, Sirs, yours faithfully,

Harley-street, W., Sept 14th, 1898. JAMES STARTIN.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—Should I in your opinion be doing anything unprofessional in giving the parent of each child vaccinated by me the following pamphlet: "Mr. A. E. Kennedy will pay the parents of any child £10 who may contract smallpox within ten years of being vaccinated by him"?

I know nothing that would so certainly convince people, and especially my anti-vaccination guardians, of the efficacy of vaccination, and I do not think I should lose my £10. But would it give professional offence?

I am, Sirs, yours faithfully,

A. E. KENNEDY,

Plaistow, E., Sept. 20th, 1898. Public Vaccinator.

*** Our correspondent must be careful to word his pamphlet so as to show that he is not claiming any particular skill for himself as a vaccinator but only acting for the good of the cause of vaccination. If this is made clear we do not think anyone will misconstrue his action.—ED. L.

THE IRISH CLUB.

To the Editors of THE LANCET.

SIRS,—May I ask the favour of a place in your columns for this letter? A number of Irishmen, for the most part resident in London, have joined together for the purpose of establishing a non-sectarian and non-political Irish Club, which will provide a central meeting-place in London for Irish residents and also for the many Irish visitors from Ireland, the provinces, and from abroad. With this object a temporary office has been taken at the address given below and a strong and representative provisional committee is being formed. May I therefore request that all Irishmen who are in sympathy with the movement thus briefly outlined will be good enough to communicate with me, when I shall have much pleasure in giving them any further information they may desire on the subject?

I am, Sirs, yours faithfully,

HENRY LENNANE, Hon. Sec. (*pro. tem.*).

11, Red Lion-square, High Holborn, Sept. 20th, 1898.

"UNTOWARD RESULTS AFTER ADMINISTERING RESORCIN."

To the Editors of THE LANCET.

SIRS,—I am not at all astonished at the experience of your correspondent "L. C." Resorcin is an escharotic of considerable power, acting chiefly on epithelium and therefore on mucous membranes. I have on several occasions employed it for destroying the granulations of rodent ulcer and epithelioma in cases where operation was refused or contraindicated. Resorcin is very soluble in water, 1 in 1, and it is not therefore surprising that, if placed in the unpowdered state, undiluted, on the delicate mucous membrane of an infant's mouth, it should produce caustic or vesicant effects. I should be very much astonished if it did not. The drug for internal administration should be diluted with some inert powder or given in some suitable vehicle. No doubt an adult might take it in the powdered state by swallowing it with a draught of some liquid without injury, but that is a very different thing from placing it on an infant's tongue, where it immediately forms a highly-concentrated and active solution. With regard to the discolouration of the specimen referred to this would either not affect its action at all or make it slightly less active. If your correspondent and his colleague had ordered 2 gr. of pure carbolic acid instead of resorcin, and the former had turned a pink colour as it does on exposure to the light, they might just as well attribute the caustic action that would follow to this discolouration as in the case referred to.

I am, Sirs, yours faithfully,

Sept. 20th, 1898. PHARMACOLOGIST.

"THE JOYS OF PLAGUE NURSING."

To the Editors of THE LANCET.

SIRS,—Will you allow me, as a nurse who has spent a good many years abroad, to say that I think it is hardly fair to so severely criticise the rules made for the plague nurses in Calcutta without knowing the special circumstances under which they were made? If I were living in a town in which rioting were taking place I should feel grave anxiety about my nurses if they went out at night unprotected and I should certainly consider myself obliged to ascertain their destination and the sufficiency of their escort; but, even apart from rioting, the whole social atmosphere is so different in India, especially in large towns like Calcutta, that I doubt very much if the liberty rightly accorded to women working at home would be understood there. I believe, for example, that in Calcutta anyone who likes to call upon anyone else is at liberty to do so, and in a country where a household of young women (apart from missionary settlements) is a complete novelty I can quite understand that the authorities may have feared that some most undesirable people might take advantage of the nurses' ignorance of Indian society and some most undesirable visitors be admitted. It was certainly hard upon the lady doctor to place upon her the onus of refusing to admit some visitors and of defending her nurses from such undesirable acquaintances, but as she was requested by the authorities to act as superintendent of the nurses her position probably brought her more into touch with the authorities and with residents in the place who knew the people and could advise her in such matters. To criticise the authorities and to blame them for "insulting the nurses" is to put a weapon into the hands of those who wish to insinuate that such rules were called for by the conduct of the nurses themselves. I cannot think for a moment that anyone wished to insult women who had come out at the call of duty and at considerable risk to themselves. The harm done was by the indiscretion of one or more among themselves or their friends by rushing into print instead of using proper means to have any rules which pressed hardly upon them altered. They were only to be in force for a short time and as soon as the rioting ceased were withdrawn. The correspondence caused great annoyance to many of the nurses who were thus forced into publicity. I may add that I think the greatest care ought to be exercised in the choice of nurses sent abroad to any position and that there ought to be an experienced committee to choose them, not entirely composed of men, and that the nurses' personal as well as professional qualifications ought to be strictly investigated and no one chosen unless the matron under whom she is working can personally recommend her for such a post. Testimonials are of little use. I know of one nurse chosen for plague duty and the matron of the hospital in which she was working was never asked anything about her: if she had been she would certainly not have recommended her for such a post.

I am, Sirs, yours faithfully,

Sept. 21st, 1898. A MATRON.

*** We did not say anything about "insult." The arrangements to which we took exception were those dealing with expenses.—ED. L.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.—The Secretary of State for the Home Department has made the following further appointments of Medical Referees under the Workmen's Compensation Act, 1897:—England: Circuit No. 6 (further appointment): Mr. Charles Hartley Bedwell Shears, Liverpool. Circuit No. 59 (further appointment): Mr. Thomas William Shepherd, Launceston. Scotland: Sheriffdom of Inverness, Elgin and Nairn: Dr. Murdo Tolme Mackenzie, North Uist.

THE ORGANISATION OF THE MEDICAL PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

THE grievances against the Plaistow Maternity Charity, as already fully described,[1] have led to the formation of a medical union called the East Suburban Medical Protection Society. The remarkable feature of this movement arises from the fact that no sooner had a few medical men gathered together to deal with one particular abuse than they discovered that there were very many other abuses which could only be met by means of united action. In an incredibly short time the multiplicity of other questions which forced themselves upon the attention of the medical men who met together to discuss their grievances in regard to the Plaistow Maternity Charity was so great that the necessity of forming a permanent union became so self-evident as to be irresistible. The main—indeed, the sole—purpose which originally had brought the east suburban medical practitioners together has now become quite a secondary consideration. If all the abuses of the Plaistow Maternity Charity were abolished or the institution itself ceased to exist the medical union which it was instrumental in bringing into being has now its hands so full of other questions that it would have to continue its work as if nothing had happened. Indeed, there are so many and such various questions claiming its attention that it has been found necessary to place the association on a thoroughly legal basis. During the first six months of its existence the East Suburban Medical Protection Society held no less than twenty committee and four general meetings. Of course, as is inevitable in such cases, a good deal of time had to be devoted to the discussing and drawing up of rules, the selection of officers, and the defining of the objects held in view. Then there arose the great question of liability. What was the legal standing of the society and the responsibility of its members with regard to the expenses incurred?

The financial question is indeed a very serious stumbling block. Of course, it may be argued that a society should be self-governed, that the members should not sanction expenditure beyond the means of the society, and that if there is a deficit this is the members' own fault, and therefore they must subscribe to make up the difference. Several objections can be made against this line of argument. The society, for instance, might be involved in some libel or other legal proceedings occasioning an expenditure altogether beyond its normal resources. Then, again, a minority of members might not be willing or might not be able to subscribe the sums voted by a majority of members. No individual member would care to pledge himself to subscribe his share of any unknown sum which a majority might decide to spend. In a word, it was thought absolutely necessary to clearly define and limit the financial liability of the members. This certainly is not the true union spirit. The members, on the contrary, ought to be ready to pay extra levies in cases of emergency. Workmen, skilled and unskilled, submit to this, and it is a difficult matter to find any arguments to show why medical men should not do as much to defend the interests of their profession as workmen do to defend the interests of their craft. However, medical men are but on the threshold of such forms of organisation, whereas the artisans of this country have had experience extending back for more than a century. In any case, and as matters now stand, it was clear that though many practitioners were willing to join a medical union they did not feel that they were in a position to assume vague uncertain financial responsibilities. Therefore, and after taking legal advice, it was found that this objection could be best met by registering the union under the Companies Acts. Thus the union has become a limited society and the financial responsibility of its members does not extend beyond the amount of their shares. The share, of course, is fixed at £1, or rather at 1 guinea, but the annual subscription is only half a guinea. It is only in the event of the society being wound up or under exceptional stress that the members may be compelled to pay the full guinea. Therefore their legal liability is limited to this small sum. Each member on joining must sign the following application form:—

"I [name in full] wish to be elected a member of the East Suburban Medical Protection and Medico-Ethical Society, Limited, and I hereby agree, if elected, to pay the annual subscription (present subscription is 10*s.* 6*d.*) and such other sums as the society may from time to time require of me, provided that such other sums shall never exceed the sum of one guinea in any year, and to abide by and obey the articles, by-laws, and regulations of the society now in force, or which may from time to time be enacted by the society in a legal manner, as provided by the Articles of Association."

For the purposes of registration the society is declared to consist of 500 members. The members are elected by the Executive Council. Three black balls suffice to exclude a candidate, but he may present himself again at a subsequent meeting. The subscriptions are due on Jan. 1st, but members elected in November or December only pay 5*s.* for that year. Members cannot ask for the help of the society unless they have paid up all dues. Those members who make a written request have a right to appear before the Executive Committee and explain their grievance. The annual subscription must be paid within one month, other calls within two months of the time when they fall due, and if the member fails to do this he *ipso facto* ceases to belong to the society, but may be reinstated at the discretion of the Executive Committee on his paying all arrears. Members wishing to leave the society must send in their resignations in writing and pay all they owe. Finally, if the acts or conduct of any member shall, in the opinion of the Executive Council and after due investigation, be considered unworthy the council may censure, suspend, or expel such member. The Executive Council consists of 20 ordinary members, and the President, vice-presidents, two trustees, a treasurer, and a secretary. These officers and the Executive Council are elected at an annual general meeting of the members. The Executive Council may fill up vacancies if they should occur between the annual meetings. It must meet at least once a month and oftener if summoned by its chairman or by 5 members of the Executive Council or 10 members of the society. It is to be noticed that it has already met 20 times in 6 months. There are, besides, rules for the keeping and auditing of accounts and the books may be inspected by all who have an interest in the society. The Executive Council has the power to employ paid agents.

Such, then, are the general rules for the governing and constitution of this new medical union. Dr. F. J. Smith, senior assistant physician to the London Hospital, was elected President and Mr. Murtaugh Houghton of Ilford secretary of the society. The members are for the most part general practitioners residing in East and West Ham, Hackney, Plaistow, Canning Town, Walthamstow, and in the various towns and districts on the line to Epping and on the line to Romford. Indeed, there is no reason why the action of the society should not extend from Aldgate to Southend-on-Sea and ultimately enroll some 3000 members. The registered office of the society is at the West Ham Hospital. Within six miles of this office there are at least 1000 medical practitioners. More than 200 have already contributed to the society's funds, though no active measures were taken to make members. It was first necessary to settle the legal position of the society. Now that this has been done systematic efforts will be made to enrol all the medical men living in east suburban London.

It was in December, 1897, that a Provisional Committee had been formed, and, as already related, a circular concerning the Plaistow Maternity Charity was issued by Mr. Charles Allen and countersigned by 51 local practitioners. That was the beginning of the society, now formally and legally constituted and governed by the rules described above. Hardly, however, had the matter of the Plaistow Maternity Charity been taken in hand than the profession was much disturbed by the proposal to employ moneys collected during the Jubilee year to open a new hospital, dispensary, and nursing institution at East Ham. 600 circulars were dispatched to practitioners likely to be affected by this new hospital, urging that it should not be supported by the profession unless at least 25 per cent. of the Managing Committee were medical men. After some negotiations this condition was accepted; thus the medical men gained their point, though their organisation was as yet only in an embryonic condition. Then there occurred some

[1] THE LANCET, August 27th and Sept. 17th, 1898.

Digitized by Google

difficulty between Dr. Vallance and the West Ham Guardians. The society came to his assistance, so that, whatever may be the merits of this case, the position of the medical man concerned was strengthened and he was not left alone to wage an unequal war against his employers, the board of guardians. Subsequently several cases arose of medical men who were advertising and others who accepted sixpenny fees. The question of a minimum fee has been more especially discussed among the practitioners of Manor Park. The population of this district is about 10,000, the majority of the inhabitants work at the building trades, and there is so much building to be done in this neighbourhood that the men are supposed to earn from 30*s.* to £2 per week. Sometimes men cannot be obtained and wages of 1*s.* 2*d.* an hour have been paid. Other inhabitants are clerks engaged in the city and many among them are poorer than the workmen. Then there are some retired tradesmen, notably publicans, and they generally own and let three or four houses. Thus the population is not poor and there is not much sickness. What, under these circumstances, should be the minimum fee? When dealing with poor people even a shilling fee with medicine included cannot be obtained if there are some other practitioners in the neighbourhood who accept less. The majority of practitioners at Manor Park charge 1*s.* 6*d.* for consultation at their surgeries and 2*s.* 6d. for visits, but some only charge 1*s.* 6*d.* for visits and one or two practitioners have given medicine and advice for 6*d.* This undercutting is so bad that now even the dispensing chemists are beginning to grumble. Thus recently a druggist having made up a prescription charged 9*d.* The customer, however, indignantly complained and argued that had he gone direct to the medical man he would have obtained both advice and the medicine for 6*d.* At Manor Park many of the local practitioners are newcomers and it is not altogether easy to get them into line nor are they yet quite agreed what the minimum fee should be; and this question has already been discussed several times by the East Suburban Medical Society. Some want to organise a medical agency and out of the multitude of suggestions and proposals made it was finally decided to draw up a list of "objects" and embody them in the Articles of Association. These so-called objects constitute a somewhat attractive programme and should help to increase the number of members. They include the obtaining of adequate representation of medical men on the governing and managing boards of medical charities. This principle we have seen has already been successfully applied at the new East Ham Hospital. Then the society is to wage the battle of the clubs, to seek to suppress medical aid societies and clubs which are not managed in an honourable and professional manner, and to do this successfully it is proposed to establish a public medical service somewhat on the same lines as those adopted at Coventry and Eastbourne. The society likewise desires to engage the services of paid trained nurses to be placed under the sole direction of registered medical practitioners. On the other hand, it will seek to prevent the public engaging the services of nurses who are employed by others than medical practitioners. The society will aid in the prosecution of persons accused of infringing any of the laws which protect the interests of the medical profession. On all such questions and whenever necessity may arise it will endeavour to approach the General Medical Council.

A new and important sphere of action will be organised. This consists of collecting outstanding debts due for medical attendance to members of the society. For this purpose it is proposed that one or more collectors should be appointed so as to save members the trouble of having private collectors of their own. Care will be taken to avoid, as far as possible, doing anything which might offend the patient. Such collectors will also receive weekly subscriptions if the patients prefer that form of payment. For this important service it is suggested that the charge should be only 5 per cent. on the amounts actually collected and this is to include postage and travelling expenses. This 5 per cent. may suffice where comparatively large sums are easily collected, but where weekly subscriptions of 1*d.* or thereabouts are paid 5 per cent. on 1*d.* or so is not sufficient for the trouble of collecting. When the collector cannot obtain the money the society's solicitors will take the matter in hand and they also will only charge a commission of 5 per cent. on the amounts collected. If it be necessary to prosecute and nothing is obtained from the debtor the member of the society will only have to pay the court fees, the solicitor's professional charges being paid by the society. Further, and as an alternative, a member may hand over his doubtful accounts if of not more than two years' standing to the society. The society will proceed at its own risks and will pay all the court and other fees, the member having therefore no risk to incur. On the other hand, should the money be recovered the society will keep one-third of the amount as its commission. This is not an exorbitant charge, for the fees payable to the treasury in County-court cases from the issuing of the summons until all useful remedies have been exhausted come to about 20 per cent. on debts which do not exceed £20. Undoubtedly a service of this description, if well organised and managed, would be of great benefit and would materially help to cement the bond of union between the members of the society.

Another form of coöperation is proposed which consists of the establishment of a medical agency for the sale of practices, negotiating partnerships, engaging assistants, locum tenents, &c., and in such cases a nominal fee would be charged. The proposal to keep and communicate where desired a black list of patients who have failed to pay their medical bills is likewise in the programme. The members will be able to obtain legal aid and advice whenever they are involved in a case which concerns the general interests of the profession. Efforts will be made to assist, by monetary donations or other means, members, their widows and orphans, in sickness, adversity, or old age. For this charitable purpose the society, in its Articles of Association, reserves the right to receive special donations and to invest funds. Finally, the society undertakes to organise professional meetings, concerts, lectures, and other entertainments, thus facilitating social intercourse and adding pleasure to business.

All this undoubtedly constitutes a very full and elaborate programme. Its complete realisation will be a work of time. Rome was not built in a day and there is a painful difference between the inception of a scheme and its realisation. Nevertheless, the society, considering that it is but in its infancy, has worked well so far. It has an energetic secretary, and that is an important consideration, nor does there seem to exist within its ranks any feelings of jealousy or any factious divisions. In other towns and districts such elements of discord have unfortunately done much to mar the success of similar movements. Therefore there is good ground to hope that the East Suburban Medical Protection Society is now fairly launched on a long career of moral and material usefulness to the members of the profession.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague in India.—Improved Prospects of Civil Assistant Surgeons.—Medical Inspection of Passengers by Rail and Boat.—The Second Report of the Bombay Plague Committee.

ON the whole plague has increased during the past week. Over 2300 deaths were reported from the Bombay Presidency and about 20 from the rest of India. It does not seem to die completely away in Karachi and in Calcutta the cases may still be described as sporadic. The general mortality is rising in Bombay and there is reason to fear that more cases occur than are reported.

A recent Government resolution with regard to civil assistant surgeons greatly increases their prospects. A senior grade on a monthly salary of Rs. 300 is sanctioned. Promotion to this grade will be made entirely by selection, the lower grades as before requiring examination. In the Bombay Presidency the assistant surgeons specially selected for the highest posts must have rendered at least 21 years' approved service. There will also be 18 civil surgeoncies to be filled by civil assistant surgeons—in Madras 5, Bombay 2, Bengal 5, North-West Provinces and Oudh 2, Punjaub 2, and Burma 2. It is also proposed subsequently to increase the number to 28. The maximum salary of these posts when in independent charge will be Rs. 500, and when temporary Rs. 350 *per mensem*. Medical inspection for plague of passengers whether by rail or sea, while it detects obvious cases of illness and thus deters the sick from travelling,

Digitized by Google

cannot ensure against the occurrence of subsequent development.

Two or three cases have arisen on outgoing steamers lately and there must be a considerable number of persons in the incubation stage who successfully pass the railway inspections. At any rate, the system reduces the dangers to a minimum, and the only alternative of quarantine for from seven to ten days is impracticable. At the various camps protecting Calcutta 7911 persons were examined during the past week, of whom 448 were detained as suspects. It is not reported that any case of plague was discovered. As Calcutta itself has shown so few cases these results cannot be put down to medical inspection, but they point rather to the absence of infected persons travelling there. The occurrence of only about 200 cases in Calcutta in three months shows the slightly infectious or contagious nature of the malady and the persistent continuation of plague in the district of Mandvie in Bombay and in Ward 8 in Calcutta emphasises once more that the habitation is the harbour of the poison.

I regret to have to record the death from plague of a lady practitioner, Miss E. Phillips. She graduated at Calcutta, but was at the time house surgeon at the Cama Hospital, Bombay. She was only twenty-three years of age.

The second report of the Bombay Plague Committee just published is of little medical interest. It is elaborately statistical and records the various regulations which were from time to time adopted during the second outbreak in Bombay. During the first three months of the year, when the disease was most prevalent, 5363 persons who had been in immediate contact with plague patients were removed to camp, and out of this number only 131 (or 2·4 per cent.) are recorded as having subsequently developed the disease. With regard to the medical inspection of the passengers and crews of incoming and outgoing vessels it is stated that from July 1st to March 31st 481,250 persons were examined coming into Bombay, of whom 38,223 were subjected to segregation. Out of this enormous number only 27 plague cases were discovered. On outgoing vessels 540,438 persons were examined and 115 plague cases only were detected. The hospital reports are particularly meagre, but they show the utterly worthless returns made from some of the private and caste hospitals. A short bacteriological report indicates how much more might have been done in this direction if some of the English medical men had been posted to this work rather than to the police-like searching for plague-stricken people to which they were allotted. What this volume shows unmistakeably is that the successive measures adopted by the Plague Committee were all carried out too late. The stable door was locked after the horse had been stolen. The measures adopted followed the course of the epidemic instead of anticipating it. Mention of the various regulations which caused dissatisfaction is candidly made, and an explanation of the disturbances which culminated in the riot of March 9th is also given. The whole volume bears witness to the unfortunate policy adopted and to the misfortunes which followed from the beginning to the end of the period with which the report deals.

Sept. 3rd.

THE SOUDAN CAMPAIGN.

(FROM OUR SOUDAN CORRESPONDENT.)

THE BATTLE OF OMDURMAN.

I HAVE just returned from Omdurman with the first convoy of sick and wounded from the battle. As far as we can ascertain the number of killed does not exceed 35, including 3 officers and a war correspondent, Mr. Hubert Howard of the *New York Herald* and the *Times*, and wounded 150.]

You will have received long ere this graphic accounts of the battle, but I may add (as one who saw the start and the finish) that it was one of the most impressive and wonderful sights of modern days, and that never shall I forget the magnificent charges of the Bagarras right up to the bayonets of our men and the splendid heroism and bravery shown by these rude warriors. The regiment that suffered most was the 21st Lancers, which had 21 killed and about 40 wounded, mostly sabre and spear wounds of a ghastly nature, in most cases severing all the structures down to the bone and causing frightful hæmorrhage from which several died. From my own station on the field I passed back during the first engagement between 50 and 60 wounded, all bullet wounds varying in severity from a penetrating wound of the skull or chest down to a concussion by a spent ball. At this early stage it is almost impossible to give any very definite ideas of the working of the various dressing stations and field hospitals, but on every side and from every mouth nothing but praise is accorded to the admirable working. Not a single man was left on the field a moment after his injuries had been attended to, and I can say without fear of contradiction that not a man was left on the field five minutes after the "cease fire" had sounded.

On our way down to this place we had ample opportunities on the boat for operating, and altogether 20 or 30 successful bullet extractions and minor operations were performed, and at the present moment all the wounded officers and men are comfortably established in this excellent hospital with every comfort which can be provided, and directly the men are fit to be moved they will be sent on. Unfortunately there is a great deal of enteric fever up the river, and at Royan Island, beyond Shabluka, they have had several fatal cases. There still remain several cases to be operated on here, where they will have the benefit of the x rays, for which a separate ward has been entirely set apart, the apparatus being one of the latest construction and perfect in every detail. Those cases in which we were unable to detect the bullets on the way down will be examined here by the rays and operated on. There remain several cases which will require operation, and this can be carried out here under the most favourable conditions.

Hospital on Line of Communication, Abadia, Soudan, Sept. 6th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE committee of the General Hospital have decided to appoint an ophthalmic surgeon and a dental surgeon to the staff of the institution. Advertisements stating the conditions of the appointments have been issued and it is expected that some keen competition will be the result. The character and tone of these offices will take their standard largely from the first appointments. The committee are therefore anxious that the best candidates should be elected irrespectively of any other considerations; they desire that they should be worthy of the traditions of this honourable charity.

The Health of the City.

The return of the medical officer of health shows a decrease in the death-rate for the first week of this month, the total being 20·3 per thousand of the population. There were no deaths from small-pox, measles, or scarlet fever. Two deaths occurred from diphtheria and 48 from diarrhœa during the week. 52 cases of scarlet fever were notified and 22 of typhoid fever. The total number of scarlet fever cases in the hospital was 172, a decrease of 9 as compared with the previous week. Considering the state of the weather and the general water-supply the returns are looked upon as gratifying.

The Conscientious Objector.

The new Vaccination Act has already brought a crop of applicants, the majority of whom while weakly reasoning strongly feel. The interpretation of the complicated provisions exhibited in the Act varies much according to the views held with regard to the right solution of the clauses. The grounds of one objector as shown at the city Police-court on Sept. 17th were novel and hardly convincing to a scientific mind. The applicant stated that vaccination would be prejudicial to the life of his child. He considered that if our Creator thought it necessary for man to be inoculated with the cow-pox He would have done so before we were born. The magistrates granted the application, though, as they stated, unwillingly. Certainly if grounds such as these are held to be sufficiently forcible the intentions of the Act will distinctly fail in securing the greatest good to the greatest number.

The Diagnosis of Drunkenness.

At a local police-court on Sept. 16th a case of alleged drunkenness was defended on the ground that the defendant

Digitized by Google

was subject to epileptic seizures. The constable who appeared in the case stated that he held a St. John Ambulance certificate and could distinguish a fit from drunkenness. The medical man called proved that he had attended the defendant for the past five years for epilepsy, from which she had suffered since childhood. The disease had become chronic and had affected the patient's mind. Her condition in such seizures might easily lead anyone to believe that she was intoxicated. Upon the evidence adduced the Bench dismissed the case. The problem still remains a difficult one to distinguish drunkenness from some diseases. Any definite signs of a fixed kind would be a welcome addition to our knowledge.

Sept. 20th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Thompson-Yates Laboratories.

THE Council and Senate of University College, Liverpool, have issued invitations for the opening by Lord Lister of the new laboratories of physiology and pathology, presented by the Rev. Mr. Thompson-Yates, on Saturday, Oct. 8th, at 3 P.M.

Distinction for a Liverpool Student.

Lord Lister, the President, and Professor Michael Foster, the secretary, of the Royal Society, have nominated Dr. S. R. Christophers, an *alumnus* of University College, Liverpool, as a member of the commission for the investigation of malaria in the British Colonies. Dr. Christophers is quite a young man, but he has devoted much time to work in the physiological and pathological laboratories of University College, where his career as a student has been a distinguished one. In 1893 he carried off the Torr gold medals for anatomy and physiology, having in the previous year won the junior gold medals in the same subjects. He was elected Holt Tutorial Scholar in 1895-96. Dr. Christophers will proceed to Italy without delay, where he will familiarise himself with the aspects of the disease in that country. Professor Golgi, of the University of Pavia, has kindly offered him all the facilities afforded by the Pavia laboratory for the study of malaria. Thence he will proceed to the Roman Campagna and later to Africa—probably to Blantyre, on the east coast. Dr. Stephens, of Cambridge University, will accompany him to Italy and Africa. His many friends here heartily congratulate Dr. Christophers upon his appointment.

Hospital Sunday in Southport.

Collections were made in the churches and chapels of all denominations in Southport and district on Sunday, Sept. 11th, on behalf of the funds of the Southport Infirmary. The infirmary has lately extended its sphere of usefulness by the addition of special departments for the eye, ear, and throat, consequently the committee appeal for an increase of funds to enable them to carry on the additional work. The weather during the morning was all that could be desired, favouring large congregations; unfortunately, in the evening rain fell for several hours, considerably interfering with attendance at church, and it is feared that the amount expected will not be realised in consequence.

Liverpool Medical Institution.

The first meeting of the session will be held on Friday, Oct. 7th. The President, Dr. W. Macfie Campbell, will deliver the inaugural address on Some Old Authors and their Books, with lantern illustrations. The President will entertain the members of the society, together with visitors who will be present in Liverpool on the occasion of the opening of the new Thompson-Yates Laboratories by Lord Lister, to supper at the rooms of the institution, followed by a smoking concert.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Ambulance Associations in Aberdeen.

THE St. Andrews and Aberdeen Ambulance Associations have now been amalgamated. The title of the new body is of formidable length, but its operations will extend to the counties of Aberdeen, Banff, Elgin, and Kincardine.

Typhoid Fever Epidemic in Aberdeen.

A serious outbreak of typhoid fever has occurred in Old Aberdeen district. This has been traced to the milk-supply from two particular dairies which the authorities have ordered to be closed. 20 cases have already been reported.

Sept. 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Nursing in the Belfast Workhouse.

THE Local Government Board have written to the Belfast Guardians enclosing a copy of a communication received from the visiting medical officers of the workhouse, in which it appears that on the date of their letter there were only 44 nurses for the infirmary for both day and night for 1500 patients, while the medical officers consider that there should be 82 nurses, of whom 22 would be engaged at night duty in order to abolish pauper nursing. The guardians appointed 15 probationer nurses on Sept. 6th, 11 of whom were to replace 11 temporary probationers, which will only increase the nursing staff to 48, while the medical officers think that 34 more would be required. Mr. Agnew, the inspector of the Local Government Board, reports that the proportion of trained nurses is altogether insufficient and the Local Government Board request the guardians to appoint an increased staff. The medical officers are most modest in only asking for 3 day nurses and 1 night nurse per 100 patients, and yet this demand repeatedly made by them has never been granted, and if pauper nursing is abolished they believe that 4 nurses for every 100 patients by day and 3 by night for every 200 patients will be required. The guardians are to consider the matter in a fortnight.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Bone Grafting.

THE end of the holiday season is already evident by the improved attendance at the various societies. At the meeting of the Academy of Medicine held on Sept. 13th M. Berger read a paper for M. Ricard upon Living Bone Grafts. The first case was that of a patient in whom M. Ricard had supplied the loss of a portion of the cranium which had been removed on account of an osteo-sarcoma. The graft was taken from the ilium of a dog. Five years later the patient was taken into the Salpêtrière with sarcomatous growth all over her, except that in the original site of operation there was no recurrence. That the graft had persisted was perceptible to the touch. It is well known that heteroplastic grafts often do disappear and are replaced by a fibrous growth so firm as to give the idea that the graft has persisted. It would have been interesting in this case to have radiographed the graft and also to have taken a portion of it for examinations so as to have had direct evidence of the persistence of the osseous tissue. The second case was that of a young woman suffering from destruction of the bony tissues of the nose. On two occasions attempts have been made to restore the shape of the nose by inserting a metal bridge, but the presence of the metal had always set up ulceration. M. Ricard split the nose in the middle line, separated the skin from the mucous tissues, and introduced between them the fourth metatarsal bone from the patient's own foot. He then united the flaps over the bone. This graft caused no irritation, but the bone mass was eventually replaced by a firm fibrous mass, which, however, enabled the nose to preserve its shape to a certain extent, although, as M. Berger remarked, the nose was too short and thick. He considers that autoplastic grafts have no very special advantages over those taken from animals and is himself disposed to use the latter.

Some Consequences of the Heat Wave.

The excessive heat prevailing in Paris for the last two

Digitized by Google

weeks has had a markedly injurious effect upon the public health. In addition to the numerous cases of sunstroke gastro-intestinal affections have run up to an unprecedented number owing to the water-supply being temporarily enhanced by water taken from the Seine, the ordinary sources of supply being insufficient to meet the demand. Some cases of gastro-enteritis have been of a very severe type, death occurring in about three days; others have been milder and very few Parisians have escaped an attack of this mild form. Every effort is being made to increase the supply of drinkable water for the town and it is hoped that by next year water from Lunain will be available. Last week an artesian well was bored at the Butte aux Cailles. This well, the boring of which was originally commenced in 1864, gives a minimum supply of 6,000,000 litres per diem at a temperature of 27° C. The water, which is very pure and appears to come from the shell beds of the Jura, will be used in part for a thermal bathing *établissement* and in part, after having been cooled down to 12° C., for drinking purposes.

The Fire at the Central Pharmacy.

A fire broke out on Sept. 14th at the great Central Pharmacy in the portion of the building devoted to the machinery and the storehouses, where are kept the finished products for immediate distribution. It was late when the fire broke out (9.30 P.M.), so that the staff had all gone. The patrol had just been round and observed nothing unusual. The alarm was given by a workman employed in the dispensary whose windows looked out upon the dispensary. The fire brigade, which arrived very quickly, were enabled to report all danger at an end after half an hour's work. The machinery shop is entirely destroyed and the fire is supposed to have originated from a spark from an electric machine having ignited some shavings.

Rabies in Paris.

Owing to the number of cases of rabies recently reported in Paris the Prefecture of Police has taken severe measures with regard to vagrant animals. M. Proust, at a recent meeting of the Board of Hygiene, expressed his approval of these measures, which consist first in the application of the regulations of May 30th, 1892, and secondly in the application of the resolution that the owner of any animal which has bitten a person should be promptly prosecuted. M. Proust has drawn up a table of the cases of rabies reported in 1897 throughout the department of the Seine. There were 351 persons treated at the Pasteur Institute, with 5 deaths—that is to say, 1·4 per cent. In 1896 there were 2 deaths; in 1895, 1; in 1894, 1; in 1893, 4; in 1892, 5; in 1891, 5; in 1890, 1; in 1889, 6; in 1888, 19; in 1887, 9; in 1886, 3; in 1885, 22; in 1884, 3; in 1883, 4; in 1882, 9; and in 1881, 21. In 1897 there were 17,700 dogs seized by the police in the houses of the public, of which number 17,241 were seized in Paris and 529 in the suburbs. Animals known to have bitten people in 1897 in Paris and the suburbs as well number 1826; of these 1594 were dogs, 84 were cats, 146 were horses, and 2 were other animals. 564 were in a state of rabies, 1212 were healthy, and 50 were unknown. 164 adults and 58 children were bitten by animals suffering from rabies, 742 adults and 407 children were bitten by healthy animals, and 34 adults and 9 children were bitten by animals whose condition was not certain. 787 dogs, 212 cats, and 3 other animals were bitten by rabid animals in 1897.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Local Application of Steam in Metrorrhagia.

AT the last Surgical Congress Professor Dührssen of Berlin made a short communication on the Treatment of Menorrhagia by the Local Application of Steam, and he has recently published an article on the subject in the *Berliner Klinische Wochenschrift*. The method was devised by Professor Snegirjeff of Moscow, who applied steam at a considerable temperature in a case of profuse hepatic hæmorrhage after the extirpation of an echinococcus, and he subsequently had recourse to it in uterine hæmorrhages. Professor Dührssen points out that a permanent cure of dangerous metrorrhagia may be effected in this way without an anæsthetic being required, and that the method is applicable in some cases for which severe operations have hitherto been considered necessary. The apparatus employed is quite simple, consisting of a boiler which is heated by a spirit lamp and from which steam is supplied by a caoutchouc tube to a metallic catheter introduced into the uterus, so that the steam from the boiler escapes through the eyes of the catheter into the uterine cavity. When steam has acted for one minute the mucous membrane of the uterus becomes white and hæmorrhages generally stop at once. After four days a second application may be made, but not for more than one minute, as the mucous membrane is liable to be destroyed by the prolonged action of steam. Professor Dührssen's first cases were three patients, one of whom was the subject of hæmophilia and suffered from menorrhagia so profuse that her life was endangered, and extirpation of the uterus had been proposed by her medical attendant. In this case the hæmorrhage was stopped by a local application of steam of two minutes' duration, but after nine days a tubular body was discharged from the uterus which proved to be the entire uterine mucous membrane together with a portion of the subjacent muscle. The patient had a second hæmorrhage thirteen days afterwards, and on the twentieth day steam was applied for the second time, after which no menorrhagia ensued. The exfoliation of the uterine mucous membrane, of course, produced complete adhesion of the uterine walls so that on examination some weeks later no uterine cavity could be found. The same was observed in the two other cases. The method is therefore contraindicated in young persons and of course in hæmorrhages due to malignant growths; but it is specially useful in profuse metrorrhagia at the climacteric period caused by chronic metritis or by interstitial myoma. To avoid adhesion of the uterine walls in young patients Professor Dührssen proposes to apply the steam for a quarter of a minute only and not to repeat it before the next menstruation. This treatment has also been employed successfully in puerperal fever, especially in septic endometritis and in subacute and chronic gonorrhœa of the cervix.

The Death of Professor Nasse.

On Sept. 1st Professor Nasse, the first assistant of Professor von Bergmann, lost his life by an accident. The deceased was an enthusiastic mountain climber and one of the leading members of the Berlin section of the German Alpine Association. Spending his holidays, as he usually did, in the Alps he had made the ascent of Mount Palu, near Pontresina, in company with Dr. Borchard and two guides. When the party were descending and were crossing a glacier a snow-bridge on which Professor Nasse was walking, suddenly gave way. The party being roped together the first guide and Professor Nasse both fell into a crevasse. Dr. Borchard and the second guide also slipped some distance, but at last succeeded in gaining a firm foothold, and both supported their companions by the rope. Unfortunately Professor Nasse had tied the rope round his chest instead of round his pelvis so that his chest was compressed by the tightening of the rope and his breathing soon became difficult. When suffocation was imminent the first guide, hoping to save Professor Nasse by taking the strain off the rope, risked his own life and cut the rope between himself and his unfortunate companion. But this sacrifice was of no avail. The two men standing at the edge of the fissure were now of course able to draw Professor Nasse out of the crevasse, but he was cyanosed and unconscious and after a few feeble respirations he died. The guide, who will become famous for his heroic action and who has justified the old-established renown of the Swiss guides, fortunately escaped death; he was found at the bottom of the crevasse having only sustained some bruises. The news of Professor Nasse's terrible death was received with the utmost sympathy among medical and lay circles in Berlin, where he had a prominent position as head of the out-patient department of the Royal Surgical Clinic. He had made a good many contributions to modern surgery and came especially into notice during the late Græco-Turkish war as leader of the German Red Cross Mission to Constantinople. Professor Nasse resided several months in the Turkish metropolis as chief surgeon to the great military hospital of that city. It was a sad coincidence that on the day of his death the Official Gazette published the news of his being decorated by the Sultan in recognition of the services he had rendered to the Turkish wounded soldiers. Professor Nasse had twice before escaped from imminent death—once on the occasion of a gas explosion on the premises of the surgical clinic, where

Digitized by Google

his skull was fractured, and once at Constantinople, where he nearly died from a poisoned wound on one of his fingers.

Spirilla in Pleuritic Exudation.

In a case of pleurisy treated in the military hospital of Munich Dr. Welke detected very peculiar micro-organisms which he has described in the *Münchener Medicinische Wochenschrift*. A soldier presented symptoms of pleurisy and pneumonia; he suffered from rigors, high fever, pains in the chest, cough, &c.; on percussion there was dulness in the left side, auscultation showed bronchial respiration with rhonchi, and an exploratory puncture gave evidence of highly fœtid purulent exudation. Before an operation could be performed a large quantity of this fluid was suddenly discharged through the bronchi, the fever decreased, and the patient recovered although very slowly. During convalescence pleurisy of the other side appeared, but passed off in a few days. In the fluid obtained by the puncture Dr. Welke discovered, in addition to leucocytes and streptococci, a great number of filiform micro-organisms which were extremely motile, displacing the leucocytes in the course of their movements. Some of them had a fusiform process at each end and their length was from 100 to 140 μ ($\frac{1}{250}$ to $\frac{1}{180}$ in.). By-and-by their motility became less and stopped altogether in from 25 to 30 minutes, when the pus had become cold. The fluid discharged through the bronchi could not be examined until after the lapse of two hours, by which time the organisms were, of course, dead. It was not found possible to classify the organisms; their great length proved that they did not belong to the bacilli and Professor Hertwig, to whom they were shown, believed them to be either spirilla or protozoa. How they had come into the pleuritic exudation could not be ascertained; probably they had made their way into the pulmonary abscess during the act of inspiration and finding this medium favourable to their development they had increased very rapidly.

Sept. 19th.

Obituary.

GEORGE WILLIS, M.D. GLASG., L.R.C.S. EDIN., L.S.A., J.P.

BY the death of Dr. George Willis, which occurred at his residence, Oak House, on Sept. 15th, the town of Monmouth loses at once its oldest medical man and one of its most prominent inhabitants. The deceased was the eldest son of Mr. George Willis, of Florencecourt, county Fermanagh, and was born in Ireland in 1828. He was the lineal representative of Captain William Willis, first High Sheriff of Fermanagh (1591), and was related to many well-known Ulster families. Dr. Willis received his medical education at Glasgow, having previously served an apprenticeship to Dr. Mahood of Enniskillen, and in 1850 graduated as M.D. at the university there, but his energetic spirit led him (before becoming qualified) to volunteer for the post of house physician to the cholera hospital during the great cholera epidemic of 1848, an act of devotion which was subsequently acknowledged by a handsome testimonial from the committee. In 1850 he also took the diplomas of L.R.C.S. Edin. and L.S.A., and married Miss Frances Spencer and settled down in Monmouth, having bought the practice of the late Mr. Thompson of that town. Dr. Willis's connexion with Monmouth therefore extended to nearly forty-eight years. He was mayor three times—namely, during the two periods 1861–63 and the period 1886–87. In his first year of office the great cotton famine brought about by the civil war in America caused serious distress in the North of England and he gained much credit by his persevering work in connexion with the local organisation for the raising of funds to relieve the Lancashire operatives. The Queen's Jubilee year was celebrated in 1887, on which occasion Dr. Willis's administrative talent was conspicuous, as he took an active part in the arranging of the festivities and popular rejoicings in the town. Working at first in the Monmouth Dispensary he persevered until the dispensary became a hospital as well as a dispensary and during the whole time his services were constantly rendered to the poor of the district. He was also surgeon to William Jones's Charity, Justice of the Peace for both borough and county, and formerly medical officer of health of the Monmouth Rural District. As a medical man Dr. Willis was shrewd and far seeing; as a friend he was staunch and true. Few practitioners contrived so well to see the best side of human nature as did George Willis, and his good humour, his good nature, and his good sense were almost contagious. Fond of the young, entering into their interests with enthusiasm, obtaining from them and their faults many of his humorous episodes, he was by them beloved, trusted, and looked up to. As a Justice of the Peace he rendered a long and useful service both to the town and the county, and as a medical officer of health he allowed few things to escape observation and remedy. Dr. Willis was a widower, his wife having died in 1892. He has left a son, the Rev. W. Armstrong Willis, rector of Llanrothal in Herefordshire. The deceased's brother, Dr. William Willis, spent the greater part of his life in Japan and Siam. An obituary notice of him was published in THE LANCET of Feb. 24th, 1894, p. 507.

RICHARD ELLIS, F.R.C.S. EDIN.

BY the death of Mr. Richard Ellis, of Rye-hill, Newcastle-upon-Tyne, the north of England loses one of her oldest and most esteemed practitioners. Mr. Ellis was in his sixty-seventh year and had been in failing health for some time past, although he was only confined to bed a fortnight before his death. He was born in Dublin and studied medicine at Edinburgh, Dublin, and London, taking his diplomas at Edinburgh. Commencing practice at Whitby he settled at Newcastle in the year 1860. In his early days he was a great and intimate friend of the late Dr. Marshall Hall and, like him, was keenly interested in the physiology of the nervous system. He was instrumental in raising funds for the scholarship established to the memory of Dr. Marshall Hall and a valued possession of his was the microscope used by that distinguished physiologist. Mr. Ellis also worked assiduously at the subject of diseases of the throat and ear, taking great interest in the Throat and Ear Hospital of Newcastle, to which institution he was at the time of his death senior consulting surgeon. He was for many years a contributor to our columns, acting at one time as our Northern Counties correspondent, and was in 1878 the Special Commissioner of THE LANCET appointed to inquire into the sanitary condition of Sunderland. Taking a great interest in all charitable agencies he was from the very first a warm supporter of the Hospital Sunday Fund. He married the youngest daughter of the late Dr. Richard Ripley of Whitby. She died some two months ago and possibly the beginning of his own illness dated from the time of hers. He was the author of "The Ear and Throat," which reached an eleventh edition, and published in our columns a paper on "The Marshall Hall Method of Treatment in Asphyxia, with case of Asphyxia from Submersion successfully treated," which was eventually embodied in Dr. Hall's work on "Drowning." He was a good microscopist and was for many years President of the North of England Microscopical Society.

DAVID EDGAR JONES, M.D. DURH., F.R.C.S. EDIN., L.R.C.P. EDIN., J.P.

DR. DAVID EDGAR JONES died at his residence, 24, Newport-road, Cardiff, on Sept. 12th. Dr. Jones was born near the town of Aberayron, in Cardiganshire, and received his medical education at Glasgow and University College Hospital, London. He took the qualifications of L.R.C.P. and L.R.C.S. Edin. in 1867 and was admitted to the F.R.C.S. Edin. in 1879. He graduated M.D. of Durham University in 1887. Dr. Jones commenced practice in Cardiff about thirty years ago and soon established a large connexion. The deceased took a great interest in municipal matters and in 1875 was elected a member of the town council; in 1885 he was appointed mayor, and in 1888 he was made an alderman. He was also a justice of the peace for the borough of Cardiff. Dr. Jones was for several years chairman of the market committee, and it was mainly through his efforts that the present excellent market buildings and slaughter-houses were erected. He was an ex-president of the Cardiff Medical Society, Government medical inspector for emigrants of Cardiff port, consulting surgeon to the *Hamadryad* hospital ship, and a visitor at the county lunatic asylum. At the meeting

Digitized by Google

of the Cardiff town council on Sept. 12th a vote of condolence was passed with Mrs. Jones, and the Mayor alluded to the assiduous and conscientious manner in which the deceased had performed his duties. On the same day the magistrates at the Cardiff police-court recorded how deeply they felt the loss of their colleague. The deceased, who was only fifty-three years of age at the time of his death, had suffered for some time from diabetes. He will be greatly missed in Cardiff, where the deepest sympathy is felt for Mrs. Jones.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the second examination for the degree of Bachelor in Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in September, the following candidates satisfied the examiners:—

Anatomy, Physiology, and Materia Medica.—First-class Honours: Alfred Parkin, College of Medicine, Newcastle-upon-Tyne. *Second-class Honours:* George Mack, College of Medicine, Newcastle-upon-Tyne; Thomas Young Simpson, Cooke's School of Anatomy; and Thomas Seymour Coates, College of Medicine, Newcastle-upon-Tyne. *Pass List:* Curtis Crispin Adeniyi-Jones and Ernest Bertram Appleby, College of Medicine, Newcastle-upon-Tyne; Arthur John Spiller Brandon and Frederick Clarkson, St. Thomas's Hospital; Francis Bernard Henry Caudwell, M.R.C.S., L.R.C.P., Charing-cross Hospital; Herbert William Dudgeon, M.R.C.S., L.R.C.P., Guy's Hospital; William Robert Davidson Daglish, College of Medicine, Newcastle-upon-Tyne; George Ernest Froggatt, Middlesex Hospital; James Herries Graham, College of Medicine, Newcastle-upon-Tyne; Ivon Henry Skipwith Hawes, St. George's Hospital; Robert Simpson Hindmarch and Albert Ernest Hodge, College of Medicine, Newcastle-upon-Tyne; Evan Llewellyn Jenkins, Cooke's School of Anatomy and Westminster Hospital; John Henry Martin, John Wilson Howard Morrison, William Athol Murray, and Alfred Henry Proctor, College of Medicine, Newcastle-upon-Tyne; Michael Joseph Quirke and Thomas Basil Rhodes, Mason College, Birmingham; Henry Reah, Stanley Raw, Frederick Riddle Scott, and William Waters Stainthorpe, College of Medicine, Newcastle-upon-Tyne; Francis Wheler Sime, Guy's Hospital; Godfrey de Bec Turtle, King's College; and Walter Wakefield, Mason College, Birmingham.

FOREIGN UNIVERSITY INTELLIGENCE.—***Berlin:*** Dr. P. Schultz has been recognised as *privat-docent* of Physiology.—*Erlangen:* Dr. Robert Heinz has been recognised as *privat-docent* of Pharmacology and Toxicology.—*Freiburg:* Dr. E. Block, *privat-docent* of Otology, has been promoted to an extraordinary professorship.—*Giessen:* Professor Karl Gaehtgens, Director of the Pharmacological Institute, is about to retire. He was formerly professor in Rostock.—*Heidelberg:* Dr. Karl Baas, *privat-docent* of Ophthalmology, has been promoted to an Extraordinary Professorship.—*Innsbruck:* Dr. Johann Rille of Vienna has been appointed Extraordinary Professor of Dermatology and Syphilis.—*Königsberg:* Dr. Rudolf Cohn, *privat-docent* of Pharmacology, has been granted the title of Professor.—*Prague (Bohemian University):* Dr. A. Vesely has been recognised as *privat-docent* of Internal Medicine.—*Palermo:* Dr. Giuseppe Cirincione of Naples has been recognised as *privat-docent* of Ophthalmology.—*Utrecht:* Dr. Eijkman, Director of the Pathological Institute in Weltevreden, Batavia, has been appointed to the chair of Hygiene.—*Vienna:* Dr. Arthur Schattenfroh has been recognised as *privat-docent* of Hygiene.—*Würzburg:* Dr. Dieudonné has been recognised as *privat-docent* of Hygiene.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall and Cox announce the following new works and new editions during the forthcoming publishing season:—A third edition of Sir William Broadbent's "Diseases of the Heart," a third edition of Professor Stewart's "Manual of Physiology," a second edition of Mr. Mayo Robson's "Diseases of the Gall Bladder," a fifth edition of Mr. Lennox Browne's "Diseases of the Throat and Nose," an eighth edition of Dr. Muter's "Manual of Analytical Chemistry," a seventh edition of Mr. Gant's "Guide to the Examination of the Conjoint Board," a fourth edition of the "Handbook for Attendants on the Insane" (under the authority of the Medico-Psychological Association), a second edition of Dr. Hime's "Guide to the Public Health Act," and the following new works just ready: "New French-English Medical Dictionary," by Mr. de Méric; a "Pocket Dictionary of Hygiene," by Mr. C. T. Kingzett, F.I.C., and Mr. D. Homfray, B.Sc.; "Cattle Tuberculosis," by Dr. T. M. Legge, secretary to the Royal Commission on Tuberculosis; Max Einhorn's "Text-book of Diseases of the Stomach"; and a translation of Professor Bollinger's "Pathological Anatomy," with atlas containing 120 coloured plates.—The Rebman Publishing Company (129, Shaftesbury-avenue) announce that from Oct. 1st next they have undertaken the publication of *Public Health*, the journal of the Incorporated Society of Medical Officers of Health.

THE DEATH OF ALICE BAYLY.—In this case Mr. John Lloyd Whitmarsh was accused of the wilful murder of the deceased, who is alleged to have died from the results of treatment designed to procure criminal abortion. The jury on Wednesday last were unable to agree on a verdict and were discharged. The accused, for whom bail was refused, will be re-tried at the next sessions.

PAUPERISM IN THE WEST OF ENGLAND.—Mr. Preston-Thomas, the Local Government Inspector for the West of England, reports that the proportion of paupers to the population in the counties of Cornwall, Devon, and Somerset (with the exception of the three unions of Bath, Bedminster, and Keynsham) is no less than 40 per 1000, being larger than in any other poor-law division. He recommended the adoption of such rules of administration as have been found effective elsewhere.

ST. JOHN AMBULANCE ASSOCIATION.—The members of the King's-cross (Great Northern Railway) Division of the Metropolitan Corps of the St. John Ambulance Association have recently presented to each of their honorary surgeons—Dr. J. Brunton, Mr. G. W. H. French, and Dr. R. Main—a cigar and cigarette case as a token of their appreciation of the lectures given during the spring of 1898. This is the sixth presentation made to Dr. Brunton and, in recognition of his services, he has also been made a life member of the association.

TORQUAY MEDICAL SOCIETY.—The president and members of the council request the pleasure of the attendance of all members of the medical profession at a special meeting of the society to be held at the Museum, Babbacombe-road, on Friday, Oct. 7th, at 4.30 P.M., to hear an address on "Gastric Perforation," by Mr. T. Pickering Pick. The seventh annual dinner of the society will be held after the special meeting, at the Torbay Hotel, at 7.15 P.M., when Mr. R. H. Grimbly will take the chair. Any medical man desiring to dine with the society on this occasion should send a postal order for 7*s* 6*d*. to the hon. treasurer of the dinner committee, Dr. H. V. McKenzie, Elm Bank, Abbey-road, Torquay, not later than Oct. 4th.

AN UNFOUNDED CHARGE.—On Sept. 15th Mr. W. E. Ryves, a medical practitioner of Paradise-square, was charged at the City police-court, Sheffield, with using instruments upon Jane Mulhern with intent to procure abortion. It was not denied that Mrs. Mulhern had miscarried, but she admitted that she had fallen downstairs two days before the miscarriage took place. Mr. McElligott said that he had seen the patient after the miscarriage had taken place and there was nothing to show that it had been brought on in any but a natural way. The chairman said that the case was not sufficiently strong to go for trial and the defendant would therefore be discharged. We congratulate Mr. Ryves on the result, for there is no charge so easy to bring, except, perhaps, that of indecent assault. We think, however, that some punishment should be meted out to those who bring such charges without, as was apparently the case in this trial, one tittle of evidence to support their charges.

THE PLAGUE IN INDIA.—We regret to say that the latest telegrams and the Anglo-Indian papers received by the last mail show that there is a recrudescence of the plague epidemic in India. The anxieties and work of the Government and its medical services will consequently undergo no abatement for the present at any rate. Unhappily, from what we know of the history of this disease, it is not surprising that the epidemic, notwithstanding the repressive measures which have been adopted, has not been eradicated and is now in its third year of existence in India. According to a telegram from Simla of Sept. 20th there were during the previous week 149 deaths in the city of Bombay, against 170 registered during the preceding week. The deaths in the districts, however, have risen to nearly 3000. 4 deaths have been reported from Karachi, 2 from Calcutta, 12 from Madras Presidency, and 8 from Bangalore City. M. Haffkine's prophylactic inoculation method has so far apparently been attended with a larger measure of success than any other. In Calcutta we are glad to say there has hitherto been no serious amount of plague.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BLACK, J. R., M.D. Edin., C.M., has been appointed Surgeon for the Greenock Infirmary, vice J. Paton.

BROWN, J. F., M.D., C.M. Toronto, has been appointed Medical Officer for the Fourth Sanitary District of the Thingoe Union.

CAIRNS, L. M., M.B., C.M. Edin., has been appointed House Surgeon for the Cumberland Infirmary, Carlisle.

COATS, G. W., M.B., Ch.B. Glasg., has been appointed a House Surgeon for the Royal Hospital for Sick Children, Glasgow.

DAHONS, ANNA, M.D. Paris, L.R.C.P. Irel., has been appointed President of the Ancoats Healthy Homes Society, Manchester.

DELANY, K., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Jamestown Dispensary District, vice T. A. Connellan, resigned.

EASTMENT, J. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Saffron Walden Union.

FELLOWS, F. M., M.B., C.M. Edin., has been appointed a House Surgeon for the Manchester Clinical Hospital, vice W. Dyson.

FULLERTON, E. C. R., M.B., C.M., has been appointed an Assistant at the Dispensary in connexion with the Royal Hospital for Sick Children, Glasgow.

GAMAN, F. R. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Caistor No. 1 Sanitary District and the Workhouse of the Caistor Union, vice Alexander Cameron, resigned, and also appointed Medical Officer of Health by the Caistor Rural District Council.

GRIFFITHS, J. C., B.Sc. Lond., M.B., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Tealby Sanitary District of the Caistor Union.

JAMES, WALTER EVELYN, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Adviser to the Monmouthshire and South Wales Employers' Mutual Indemnity Society for the County of Monmouth.

KELLY, M. T., M.D., B.S. Dubl., has been appointed Medical Officer for the Workhouse and the Coddenham Sanitary District of the Bosmere and Claydon Union.

LEITCH, JOHN W., M.A., M.B., Ch.B. Glasg., has been appointed Junior Assistant Medical Officer for the Counties Asylum, Carlisle, vice T. D. Bell, resigned.

MCCULLOCH, EDWARD, M.B., Ch.B. Edin., has been appointed an Assistant House Surgeon for the Royal Albert Hospital, Devonport.

MUIR, D. K., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the South Longbenton Sanitary District of the Tynemouth Union.

NUNN, P. W. G., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Pokesdown District Council.

PROCTER, G. L., M.B., C.M. Edin., has been appointed Medical Officer for the Dawley Sanitary District by the Madeley Board of Guardians.

RENWICK, A. C., M.B., Ch.B. Edin., has been appointed House Surgeon to Noble's Isle of Man Hospital, Douglas.

REYNOLDS, F. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Superintendent for the Corporation Hospital by the Bootle Town Council.

SPRAGUE, W. C., M.D. Edin., M.S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Seventh Sanitary District of the Saffron Walden Union.

SUTTON, W. L., has been appointed an Analyst for the Borough of Ipswich, vice J. Napier.

WARREN, ERNEST D., M.R.C.S., L.R.C.P., has been appointed Senior Assistant Medical Officer for the Counties Asylum, Carlisle.

WRENCH, E. B., M.B., B.C. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Baslow Sanitary District of the Bakewell Union.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

ADDENBROOKE'S HOSPITAL, Cambridge.—Resident House Surgeon.

BURY INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board, residence, and attendance.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House Surgeon. Board and residence provided in the Hospital.

CHELSEA, BROMPTON, and BELGRAVE DISPENSARY, 41, Sloane-square, S.W.—Surgeon.

CROYDON GENERAL HOSPITAL.—House Surgeon for two years, unmarried. Salary £100, increasing £10 per annum to £120 with board and residence in the hospital.

GENERAL INFIRMARY, Leeds.—Resident Ophthalmic Officer. Salary £50 a year, with board and lodging.

GREAT YARMOUTH HOSPITAL.—House Surgeon. Salary £90 per annum, with board and lodging, No wines, spirits, beer, &c., provided.

HEREFORD GENERAL INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished rooms, board, washing, gas, coals and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—Resident Medical Superintendent for one year. Salary £105 a year, with board and residence in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

DUNCAN.—On Sept. 13th, at Eccleston-street, S.W., the wife of Duncan Duncan, M.R.C.S., of a daughter.

EDWARDS.—On Sept. 18th, at Halling, Rochester, the wife of Arthur Spencer Edwards, M.B., C.M. Edin., of a son.

WHITMORE.—On Sept. 20th, at Bryanston-street, Hyde-park, the wife of W. T. Whitmore, F.R.C.S., of a son.

MARRIAGES.

DEAN—HOPE.—At the Free Church Manse, Banff, on the 16th inst., by the Rev. And. Melville, D.D., Edinburgh, uncle of the bride, George Dean, M.A., M.B., C.M., British Institute of Preventive Medicine, London, to Laura Hope, daughter of the Rev. J. Watson Geddie, B.A., Free Church, Banff.

CHALMERS—CANNINGTON.—On Sept. 21st, at Wesley Chapel, Waterloo, by the Rev. H. J. Pope, D.D., of London, uncle of the bridegroom, assisted by the Rev. T. Hardwick Mawson, of Newcastle-on-Tyne, Albert John Chalmers, M.D., F.R.C.S., younger son of the late Rev. James Chalmers, M.A., to Alice, second daughter of Edwin Cannington, J.P., of Beach Lawn, Waterloo, Lancashire.

GOOD—GORDON.—On Sept. 14th, at St. Paul's, Hammersmith, Hardman Allgood Good, M.R.C.S., L.R.C.P. Lond., second son of the late Rev. Edward Good, R.N., to Frances Louise Innes, youngest daughter of the late James Richard Gordon, Medina-place, N.W.

DEATHS.

ELLIS.—At 100, Rye Hill, Newcastle-on-Tyne, on the 14th inst., Richard Ellis, F.R.C.S. Edin., in his 67th year.

WILLIS.—On the 15th inst., at Oak House, Monmouth, George Willis, M.D., J.P. County of Monmouth, in his 70th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1898, which was completed with the issue of June 25th, and the Title-page to the Volume were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1898, bound in cloth, gilt lettered, price 18*s.*, carriage extra; and Cases for binding the half-year's numbers, cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*, can be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

DEATH FROM ABORTEFACIENTS.

AT an inquest recently held upon the body of a woman who died near Godalming evidence was given that the death was due to the deceased having taken some pills to produce abortion. The box containing the pills bore a Government stamp and a label stating that they were prepared by a physician formerly of the "Women's Hospital, Soho-square." The coroner remarked that something ought to be done in the way of legislation to prevent the wholesale sale of such noxious drugs and the jury added a rider to their verdict to the same effect. We quite concur in this, and, moreover, any paper which publishes any advertisements of pills or other means of removing obstructions should be heavily fined. Something ought also to be done to put a stop to businesses such as that of Madame Frain.

COUNTRY HOUSE DRAINAGE.

To the Editors of THE LANCET.

SIRS,—You would confer a benefit on a number of householders by solving the following sanitary problem. Most of the country houses in this neighbourhood drain into separate cesspools, situated generally 50 yards or so from the house and receiving the waste from water-closets, kitchen sinks, and rain-pipes. These cesspools are usually pits measuring about 6 ft. every way, lined with dry stonework—i.e. large stones set without mortar or cement. They are covered in with tarred timbers on which the grass sod is laid. When not too full and in dry weather, percolation disposes of a good deal of the water received, but all are provided with outfalls discharging into field ditches. The problem is how to deodorise the effluent. My house and an adjoining one drain into a common cesspool through a 6 in. pipe furnished with Buchan trap and ventilating shafts. The closets of both houses are fitted with three-gallon syphon cisterns. The two houses combined contain fourteen persons. Owing to faulty levelling the first part of the ditch which receives outfall contains a good deal of water. This portion measures about 90 yards, and is best described as a black-water ditch, offensive when stirred. During a course of another 200 yards the ditch becomes much cleaner, and is ultimately nearly empty and quite inoffensive. Once a year after the leaves have fallen I have the whole ditch cleaned out. I should be very much obliged for advice as to how the black part of that ditch can be deodorised. What is wanted is a direction as to the quantity of deodorising substance to be added to sewage per head of house inhabitants. The cheaper the substance the more widely it will be used. I may mention that the water-supply of the whole district is derived from the Vartry Waterworks, so that no question of water-pollution arises.

I am, Sirs, yours faithfully,

Sept. 10th, 1898. SOUTH DUBLIN.

*** We deal with the subject of this letter in an annotation.—ED. L.

THE NATURE OF DRY-ROT.

To the Editors of THE LANCET.

SIRS,—I shall feel much obliged if any of your readers, more particularly medical officers of health in Scotland, will inform me if dry-rot in a house is considered a reason for serving a notice on a landlord to effect reparations by the sanitary inspector. I can understand that the landlord may be responsible for putting the floors affected into repair and that if an accident were to occur by putting one's foot into it—i.e., the floor giving way and so causing fracture, &c.—he would be responsible civilly. But I should like to know if it is considered that dry-rot in a house is noxious to health, and if a sanitary inspector is justified in serving a notice on the proprietor to remedy it. If any of your readers can give me some hints as to the prevention and cure of that plague I shall feel very much obliged. And there is another point I should like cleared up. I always believed that dry-rot is a fungus attacking wood *only*. Now I am told by practical men that it also attacks stone. This is, I must say, very hard to believe, and I shall be very much obliged for some references to the literature of the subject. Up to the present time it has cost me a great deal of money and is continually breaking out, and I never know when I shall be called upon to pay from £20 to £50 to get rid of it.

I am, Sirs, yours faithfully,

Sept. 17th, 1898. AFFLICTED.

HYGIENE AT ALGIERS.

A TRAVELLER in search of an ideally hygienic city would scarcely direct his footsteps towards Algiers, and yet the chief civic dignitary in that odoriferous town is clearly imbued with some sound if rather advanced notions regarding cleanliness and the spread of disease. Seeing that articles of food are habitually wrapped up in fragments of paper, such as old journals, obsolete registers, pamphlets, and printed or written matter of various kinds which might before being so employed have passed through the hands of people following diverse occupations who may perhaps have been affected with infectious or contagious diseases and in this way have become contaminated, possibly acquiring the most dangerous properties without even appearing soiled, the practice cannot but be considered prejudicial to the public health and should therefore be rigorously interdicted. Having introduced his subject in a preamble to the foregoing effect the Mayor of Algiers recently issued the following *arrêté* for the information and guidance of the citizens under his control. 1. No painted or stained paper of any description whatsoever shall on any account be employed for the wrappage of alimentary substances. 2. Printed paper, old journals, pamphlets, miscellaneous works, registers and other manuscripts can only be tolerated for the wrappage of dry vegetables, roots, or tubers (dry kidney beans, potatoes, &c.), but in every case the sheet must be free from stain. 3. The police, with the help of the municipal laboratory, will exercise a permanent control in order to satisfy themselves of the cleanliness of the paper used. In a postscript to this remarkable ordinance a list as follows is furnished of moist alimentary substances which must invariably be wrapped up in fresh clean paper, which may be either white or straw-coloured but on no account spotted or stained: butchers' meats, meats of all kinds which are sold retail such as rabbit or poultry, pork, pastry, confectionery, butter, grease, cooked or steeped vegetables, vegetables sold in slices such as pumpkins, fresh or early vegetables, salt or soaked fish, and fresh fish sold retail.

VULGAR METHODS.

WE are informed by a correspondent that he has recently seen a bottle decorated with the following three labels:—

[*Red label in front of bottle.*]

Special advantages are offered to Married Women. Twenty years' sound practical experience, during which period over 4000 Midwifery cases have been attended.

[*White label in front of bottle.*]

H. H——, Physician, Surgeon, Apothecary, &c., L.R.C.P.I., L.M., L.F.P.S.G., and L.S.A. Lond., &c.,
111, Plashet-grove, East Ham.

NOTE.—Dr. H——, for many years of the firm of H—— and J——, Battersea Park, formerly of H.M. Transport Service Egyptian Campaign, and late of H.M. West African Military Service, may be consulted daily, morning before 12; evening 6.30 to 9.

[*Red label on back of bottle.*]

Deafness, Diseases of the Ear and Throat, and the Diseases incidental to Women and Children, receive special attention.

There can be no doubt that to label medicine in such a way is to employ methods which are generally considered beneath the dignity of the medical profession.

THE NEW HARVEY.

WE have received a little pamphlet from M. J. Rodormund, M.D., of Appleton., Wis., which is a reprint of his address delivered before the National Medical Association held at Omaha in June, 1898. Dr. Rodermund is described as "the first physician to discover the law and power that propels the blood." He also sends us an illustration of himself from a photograph. The power which propels the blood is not, as we have all been wrongly taught for the last 250 years or so, the heart. No; it is the same power as that "which furnishes the motive power throughout universal nature." We quote Dr. Rodermund's own words:

> "Instead of the blood carrying oxygen through the system it is the oxygen from the air that sends the blood bounding through all the minute capillary blood-vessels, exactly reversing the old theory that has been believed by us all for nearly three centuries. In other words, it is the oxygen we breathe based on the fundamental law of electricity.
>
> "You all know that all positive electric bodies proportionally repel, while all negatives and positives attract each other; hence this oxygen or electricity, both elementary the same, is one of the chief agents and means of life, and is introduced into the system by breathing and nothing else. This air when breathed charges the air-cells of the lungs when the iron in the blood attracts the oxygen; this charges both the air and the blood-cells positively, and thereby generates a powerful self-acting propelling force by each repelling that in the other.
>
> "Is not this problem plain as well as simple? That it is the oxygen from the air we breathe, and not muscular contraction of the heart that gives this tremendous power to push the blood through this fine network of blood-vessels throughout the body. And this force not like dynamic pressure which would strain or even burst the heart, while the other works on a different principle—that of mutual antagonism and not of pressure."

Of course we cannot prove that oxygen is not electricity, but Dr. Rodermund's arguments are not convincing.

WANTED DIAGNOSIS AND TREATMENT.

To the Editors of THE LANCET.

SIRS,—Can any of your readers suggest any cure or palliation of the following miserable condition? Every ten days or a fortnight I am awakened about 4 or 5 A.M. by a headache which gradually gets worse and worse as the morning goes on, until about 1 or 2 P.M., when it becomes unbearable. The pain is generally over first the right, then the left temple, and at the back of the neck and head and upper part of the interscapular regions, chiefly over the seventh cervical and first dorsal vertebræ. At this time, and only when the pain is on the neck, I notice audible cracks on movement, and the feeling is like the pain from a heavy blow at the back of the neck. During the whole time I am unable to eat or drink anything except hot water, which I generally

Digitized by Google

drink freely, and which, after a time, by making me vomit, seems to relieve me. As the attack robs one of a day's work it becomes a most serious affair. I have tried all the remedies usually recommended in such cases without effect. The only medicine that gives the least relief is an effervescing draught with some bromide and antipyrin and gripping the neck tightly over the carotid arteries. I come of a gouty race and my father was a martyr to headache most of his life. I am in my fiftieth year. Any suggestions will be most gratefully received by

Yours very truly,

Sept. 20th, 1898. L. M.

"THE MEDICAL DIRECTORY."

To the Editors of THE LANCET.

SIRS,—The desire of your correspondent, "Subscriber of Twenty-five Years' Standing," in THE LANCET of Sept. 17th is one we would gladly comply with were it not for the fact that when in the year 1890 we took steps to know the opinion of the profession we found that less than 14 per cent. of the registered practitioners expressed themselves in favour of an amalgamation of the various local lists. Opinions proverbially differ, but it is evident that we consult the wishes of the majority by an adherence to the present plan.

We are, Sirs, yours faithfully,

Great Marlborough-street, Sept. 19th, 1898. J. & A. CHURCHILL.

To the Editors of THE LANCET.

SIRS,—I agree altogether with the remarks of "Subscriber of Twenty-five Years' Standing" in THE LANCET of Sept. 17th as to the inconvenience of placing Wales in a separate section of the Medical Directory. The inconvenience, moreover, is greatly increased by the remarkable fact that Monmouthshire, one of the 40 English counties, is included in the Wales section. Some time back I ventured to call the attention of the editors to this point and I gave them an instance of a young Monmouthshire medical friend who had been put to considerable inconvenience and had been placed under some temporary suspicion in consequence of his name not appearing in the Provincial section of the Directory. It naturally had not occurred to the inquirer to search for his name in the Wales section. I received a courteous reply that the matter would be considered, but still the Directory, in defiance of history, law, and custom, deprives England of one of her counties and makes Wales to consist of thirteen counties. Perhaps the editors may even now reconsider the matter and remove this blemish from their indispensable and otherwise remarkably accurate publication.

I am, Sirs, yours faithfully,

A MONMOUTHSHIRE SUBSCRIBER OF THIRTY

Sept. 17th, 1898. YEARS' STANDING.

"THE LATE ARTHUR JEFFARES BARLOW."

THE following subscription to the fund for the widow of the late Mr. Barlow has been received by Dr. J. Agar Matson:—Dr. W. Brooks, £1 1s. We are requested to state that Dr. J. W. Moore of 40, Fitzwilliam-square, Dublin; Dr. J. Agar Matson of 119, Holloway-road, London; and Dr. J. P. Henry of 2, Lewisham-park, Lewisham, will continue as heretofore to receive donations on behalf of Mrs. Barlow.

SIC VOS NON VOBIS.....

FILIAL piety received a rude check at Clerkenwell police-court on Sept. 19th. An enterprising dairyman had, it appears, recently been fined £10 12s. 6*d.* for adulterating milk. Accordingly his son, Henry David Welch, and a friend, by name Pettit, started forth with an appeal relating the sad circumstances and expressing a hope that Mr. Welch's friends would rally round him. Unfortunately an unsympathetic constable apprehended the prisoners after they had endeavoured to get a subscription from a dairyman in St. Pancras. Welch junior said he did not think he was doing any harm in collecting money for his father. Mr. Horace Smith, however, took a hard-hearted view and bound over both defendants to keep the peace.

TWO QUERIES.

To the Editors of THE LANCET.

SIRS,—Will you please inform me whether (*a*) when called to a case of cut-throat and having attended it the doctor is found to communicate with the police or see that the police are informed; (*b*) if a woman comes into a consulting-room and asks the doctor to perform abortion or to administer drugs for that object, what is the precise legal obligation of the doctor? I am, Sirs, yours faithfully,

Sept. 15th, 1898. VERAX.

*** General rules will not hold good in these matters under all conceivable circumstances, but (*a*) it is no business of the medical man to act as an informer, and (*b*) he would be legally correct in sending for the police. In the second case he has been distinctly invited to commit a crime and such invitations are themselves criminal.—ED. L.

Mr. Clarence Beesley.—The office of the society is at 19, Buckingham-street, Adelphi, W.C., and all information will be given by the honorary assistant secretary.

Mr. Ernest Cox.—We do not give medical advice. The case is one, as described to us, where the opinion of a physician at a hospital might fairly be sought.

HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested Milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal*, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says:—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

MOUNTJOY BREWERY, LTD.

(Late FINDLATER & CO.),

RUSSELL STREET, DUBLIN.

NOURISHING STOUT.

THE attention of Medical Men is respectfully called to the value of this finest of Malt drinks as a valuable Tonic Restorative. Numerous Unsolicited Testimonials have been received by our Bottlers all over England.

SAMPLES will be sent direct from the BREWERY, Carriage Paid, with name of nearest Bottlers, on application.

ANALYTICAL RECORD FROM "THE LANCET."

"CROWN STOUT.—MOUNTJOY BREWERY, RUSSELL STREET, DUBLIN.

"The nourishing qualities of Stout are due mainly to a comparatively high proportion of Malt extractions, which, consisting principally of maltose and dextrine, offer little task to the digestive organs. The sample before us is marked by an excellent proportion of these extractions, while, at the same time, the alcoholic strength is by no means excessive.

"The results of analysis were as follows: Malt extractions, 9 0 per cent.; mineral matter, 1·38 per cent.; alcohol—by weight 4·62 per cent., by volume 5·78 per cent.; equal to proof spirit 10·13 per cent. The mineral matters consisted almost entirely of soluble potassium phosphate. The Stout was in good condition, ripe, yet free from undue acidity, and possessed a characteristic malty flavour."

SIR CHARLES CAMERON'S ANALYSIS.

"DUBLIN.

"I have analysed a specimen of **Nourishing Dublin Stout**, submitted to me for that purpose by **The Mountjoy Brewery, Dublin.** I have never examined a specimen of Porter in which the solid or nutritive constituents were so abundant as in the case of this Stout. It contains **Ten Per Cent.** of its weight of solid matter, or nearly the amount of solids contained in milk. Its flavour is good, and it is **Remarkably Free from Acidity.**

"CHARLES A. CAMERON,

"*Professor of Chemistry, College of Surgeons, Dublin.*"

PROFESSOR TICHBORNE'S ANALYSIS.

"DUBLIN.

"I have examined and analysed for several years the Stouts brewed by **The Mountjoy Brewery**—viz, **Single, Extra,** and their speciality known as **Nourishing** or **Crown** Stout. The gravities of all these Stouts are very high, as proved by my analysis. **The Crown** or **Nourishing** Stout gave me one of the highest gravities I have ever seen in Stout. They are all of first-class quality. **The Nourishing** Stout being exceptionally fine, and owing to its **strength** and **purity,** is a most valuable food for **Invalids.** They are all brewed from **Malt** and **Hops only,** the water used being the best brewing water the City of Dublin affords.

"CHARLES R. C. TICHBORNE,

"*Professor of Chemistry, Dublin.*"

Ergot Aseptic,

(P., D. & CO.)

An Ideal Preparation of Ergot for Hypodermic Administration.

Extractive matter is inert and causes abscesses. Ergotinic acid is a nerve depressant and irritant. Aside from being entirely free from both extractive matter and ergotinic acid, Ergot Aseptic is

Physiologically Tested, Standardized, and Sterilized.

Put up in hermetically sealed glass bulbs, which exclude all germs or other contaminating substances. No necessity therefore for alcohol, glycerine, salicylic acid, or other preservative, which might prove irritating. Each bulb contains one cubic centimetre, representing two grammes of standard Ergot.

IT IS VERY RAPID AND POWERFUL IN ITS EFFECTS, PRODUCING STRONG UTERINE CONTRACTIONS WITHIN A SURPRISINGLY SHORT TIME. . . . . .

You may convince yourself of the superiority of Ergot Aseptic by the following simple test: Take two test tubes. Pour into one a small quantity of Ergot Aseptic, and into the other an equal quantity of any one of the ordinary preparations of Ergot on the market. Add to each from three to five volumes of alcohol. Ergot Aseptic remains clear; the other is precipitated.

LITERATURE UPON REQUEST.

A NEW HYPODERMIC CASE.

We have recently devised a neat case, covered with fine leather, containing our Hypodermic Syringe and two fortified needles, together with TEN TUBES of Hypodermic Tablets and TWO BULBS of ERGOT ASEPTIC. Price complete, 17/6.

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic,** we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialties—

ELBERFELD FARBEN FABRIKEN CO., Ld., 19, St. Dunstan's Hill, LONDON, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

COX'S TASTELESS PILLS

Our Mr. Cox invented PEARL COATING to render Pills TASTELESS more than fifty years ago.

THE PATENT WAS DATED AND SEALED APRIL 13th, 1854.

Of course success like this has produced the inevitable copyist; our prices, however, will be found to compare most favourably with any makers where best drugs and chemicals are used, and we pay all carriage and postage.

In order to secure our goods, and to avoid the possibility of others being substituted, please see that all packages bear our name and trade mark.

Our JULY, 1898, Catalogue, containing over 800 formulæ, including the most approved new remedies suitable for pilular form, post free (with samples if required) upon application.

N.B.—We make and sell nothing but Pills.

ARTHUR H. COX & CO., BRIGHTON.

"A perfect combination of Malt Extract and Cod-liver Oil."—*British Medical Journal.*

BYNOL

The "PERFECTED" Malt and Oil.

BYNOL, though containing a much larger percentage of COD-LIVER OIL than the ordinary preparations of MALT and OIL so widely sold, is, nevertheless, not only free from all unpleasant taste, but has a most agreeable nutty flavour, so that it is relished as a sweetmeat by many children. It can be taken without difficulty by delicate patients, being readily digested and assimilated. This result is due in large measure to the intimate combination of the MALT EXTRACT with the OIL, globules of the latter not being distinguishable even under a microscope.

The Malt Extract employed is exceptionally nutritious and active, while the Cod-liver Oil is of absolute purity, being made at Allen & Hanburys' own factories in Norway, from the fresh and selected livers of the Cod-fish only. *SAMPLES FREE TO MEDICAL MEN.*

The late Sir ANDREW CLARK, in a lecture at the London Hospital, remarked:—

"I have said that these fibroid cases are poor creatures, thin and white, and have what may be called nutritive debility, and the question is, What am I to do with them? You cannot do better than endeavour to make the patient walk in the way of physiological righteousness. But that sometimes will not do. Some people may be physiologically well behaved, and somehow they do not thrive on it. Can you do anything in those cases? There are two remedies which sometimes do succeed where the ordinary diet will not succeed in nourishing the patient—the one is Cod-liver Oil and Malt given with food—a preparation called **BYNOL**—*and the other is the remedy called* **BYNIN EMULSION,** *consisting of Hypophosphites, Oil, and Malt; both are prepared by Messrs. ALLEN & HANBURYS. These are two good nutritive agents in promoting nutrition."*

ALLEN & HANBURYS Ltd, Plough Court, Lombard St, LONDON, E.C.

PEPTOGENIC MILK POWDER

PEPTOGENIC MILK POWDER renders cows' milk just as digestible as mothers' milk.

Cows' milk treated with the **PEPTOGENIC POWDER** becomes the closest possible approximation to mothers' milk in every detail—percentage of all constituents, and character of albuminoids.

THE FUNDAMENTAL DIFFERENCE between cows' and human milk is in the character of their albuminoids. The caseine of cows' milk when ingested coagulates into tough indigestible masses, while that of human milk remains diffused, soluble, and therefore easily digestible.

THE PEPTOGENIC POWDER and method afford a reliable and practical means of adjusting this difference.

Supplied to the Medical Profession in ½ lb. and 1 lb. bottles at 1s. 9d. and 3s. 4d.

PANOPEPTON

PANOPEPTON being the entire edible substance of prime lean beef and best wheat flour, is the food par excellence for invalids in all acute diseases, fevers; &c.; in convalescence for the large class of persons who, from feebleness or deranged digestion, or antipathy to ordinary foods, require a fluid, agreeable, and quickly assimilable food.

For an adult the usual portion should be a dessert-spoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles at 2s. and 3s. 4d. each.

PEPSENCIA

PEPSENCIA is a palatable and effective digestive fluid. It contains all the constituents of the gastric juice. A teaspoonful before or after meals will be found of service in all cases where pepsin is indicated.

Supplied to the Medical Profession in 4 oz. and 8 oz. bottles at 1s. 9d. and 3s.

Specimens and literature will be forwarded on request.

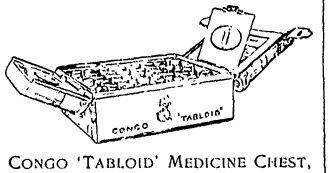
TRADE MARK 'TABLOID' BRAND



Medicine Cases and Chests

NO. 16A.
'TABLOID' POCKET MEDICINE CASE.

NO. 20.
'TABLOID' MEDICINE CASE.

CONGO 'TABLOID' MEDICINE CHEST,
AS SUPPLIED TO H. M. STANLEY.

'TABLOID' Medicine Cases are the most compact and portable outfits it is possible to obtain for home use or for abroad. They are fitted with 'Tabloid' Compressed Drugs, thus securing pure and active medicines in the smallest possible space.

The great convenience, portability, preservability and therapeutic activity of 'Tabloid' Drugs have been repeatedly proved by the experiences of medical officers in all parts of the world.

A large variety of cases is made, in calf, raw hide, morocco, crocodile, pig skin and other leathers, suitable for the pocket, the cycle or the carriage.

Special outfits may be had for abroad, and any case can be fitted to suit individual requirements.

Full particulars and lists will be gladly sent on request.

ABSTRACT OF AN

Address

ON

THE MEDICAL PROFESSION AND THE STATE: THEIR RELATIONSHIP, ESPECIALLY WITH REGARD TO VACCINAL LEGISLATION.

Delivered by

JOHN C. McVAIL, M.D., D.P.H. CAMB., F.R.S EDIN.,

PRESIDENT OF THE CONFERENCE OF MEDICAL OFFICERS OF HEALTH HELD IN BIRMINGHAM ON WEDNESDAY, SEPT. 28TH, IN CONNEXION WITH THE ANNUAL CONGRESS OF THE SANITARY INSTITUTE.

GENTLEMEN,—In such a meeting as this the subject can perhaps be best approached by referring to the relationship of medical officers of health to their local authorities. As is so well urged by Dr. Alfred Ashby in his article in Stevenson and Murphy's Hygiene, the medical officer must be prepared from time to time to submit with equanimity to the rejection of any advice which he may tender to his local authority, however sound such advice may have been; nor must he be too sensitive in the event of his advice or actions being misunderstood or misconstrued. He must bear in mind that the decision of his local authority may have been subject to considerations which had no weight with him. It is, however, his duty, if he finds that his advice is systematically and persistently ignored and that the health of his district is likely to suffer, to repeat such advice, again and again if need be, firmly but dispassionately. He should further endeavour to look at all questions, not merely from the view point of the specialist in public health, but also from that of the local authority and of the owners and occupiers of premises and of the public. Of course, the medical profession is not related to the State so closely or directly as is the health officer to his local authority. The profession is not paid out of public funds in the same way as the public health service is. But only persons legally qualified in medicine can perform the many functions which bring us as a profession into very close relationship with the State and which give us in great measure the position of advisers regarding the means to be used by the State for the prevention of disease and the improvement of the physical well-being of the people. This is a position, indeed, which the profession has not hesitated in many circumstances to assume as its own. A clear distinction should, of course, be made between this professional position and our individual position as units in the general community; but if there is anything in the analogy which I have ventured to draw, then it is our professional duty to declare with no uncertain voice, and to repeat as often and as urgently as may be necessary according to the greatness of the emergency, our deliberate judgment on methods of disease prevention and health conservation. But it would be a mistake to assume that our conclusions, though their truth be demonstrated and be freely acknowledged by the legislature, will necessarily be embodied in Acts of Parliament and, in their practical application, be enforced by pains and penalties.

Let us apply these considerations to the question of vaccination. Speaking to an audience of health officers—speaking especially after some 1100 of us have testified by signed declaration that vaccination and revaccination prevent and control small-pox and that small-pox cannot be effectually prevented and controlled without these means—I need not spend time in urging the value of the Jennerian prophylaxis. But for the present purpose I shall assume further that the legislature is equally convinced (1) that small-pox is a disease which ought to be prevented; (2) that it can be safely prevented by vaccination and revaccination; and (3) that it cannot be prevented by any other known means. Does it then unavoidably follow that vaccination should be compulsorily enforced? Can nothing be conceived capable of justifying Parliament in refraining from enacting a power of absolute coercion? Small-pox is an evil—a very terrible evil—but there are other evils besides small-pox, and it is sometimes necessary in mundane affairs to make a choice of evils. Let us suppose that Parliament is, rightly or wrongly, of opinion that in many places in England the opposition to vaccination is so deep-seated that its attempted enforcement could be carried out only with the aid of an army of soldiers or would involve the wholesale imprisonment of large communities. Surely, in such circumstances Parliament is right in endeavouring to weigh and measure the two evils and to choose the less. It may make a wrong choice and the country may have to pay for the error, but the medical profession has no need to feel injured or aggrieved. The crucial fact is that the decision of such matters is a function of the legislature and of the legislature only, and where the duty is there the responsibility must rest. The words "expediency" and "opportunism" are not popular. They are apt to suggest the attitude of Bunyan's Mr. Facing-both-ways. But opportunism may after all be the truest Statesmanship, and the man who supports a temporary relaxation of a compulsory law may be the best friend of the administration of that law. In Scotland we are, so far, in the happy position of not requiring this measure of expediency. The vaccination default, instead of being over 30 per cent. as in England, is less than 3 per cent.

Let it be understood that in all this I am not discussing in concrete fashion the merits or demerits of the new Vaccination Act, nor is it my purpose to do so here. In this meeting we are probably all heartily agreed that revaccination as well as primary vaccination requires legal provision; that sanitary authorities instead of poor-law authorities should have charge of vaccinal administration; that all required vaccination prosecutions should be conducted not by local authorities but by public prosecutors; that vaccination certificates of private medical men should be paid for by the State as are similar certificates by public vaccinators; and that all vaccination certificates should place on record the area and number of marks. These points and others, however, have been discussed very fully in the medical press and elsewhere and they need not detain us, especially as there is good reason to hope that next session of Parliament will see the introduction of a Revaccination Bill. Regarding the conscience clause we may as a profession be satisfied that our withers are unwrung. In this country vaccination though called compulsory has never been compulsory. The whole question is between one degree of pressure and another. The greatest pressure has been by repeated penalties. Imprisonment for non-vaccination has never taken place. It is the common law of the land that in the last resort people who refuse to pay legally inflicted fines may be imprisoned, but that applies to fines for infringement of the Vaccination Acts in the same way as to fines for the infringement of other Acts. Therefore, I say, repeated fines have been the maximum legal pressure ever brought to bear in favour of vaccination. Limitation in the number of money penalties means simply a less degree of pressure. The recognition of what is technically called conscientious objection is assumed by most people to be a further step in the same direction. Whether it will really turn out to be so time alone can tell. Under the old system vaccination had within recent years come to be a matter of local option, and in many places where the option went against vaccination no pressure of any kind was brought to bear upon individuals. But under the new law Mr. Chaplin has indicated that where boards of guardians fail the Local Government Board will see that the subject is definitely brought before parents and that if the visit to the petty sessions is not made within the stipulated time the law and the penalties attached thereto will be enforced. In fact, individual option will take the place of local option, and it would be rash to prophesy that under the new system the vaccination default will be greater than, or as great as, under the old. If all legal or artificial pressure were abolished there would come into force increasingly the strongest natural pressure—that of small-pox itself. It was the world's intimate knowledge of the dreadful power of variola and its quickly gained experience of the counteracting power of vaccinia that brought about the wide triumph of the preventive in the early part of this century. It may seem paradoxical, but there is a sense in which it is correct to say that the growing neglect of vaccination is the greatest centenary tribute to the memory of Edward Jenner. A century ago everybody knew and dreaded small-pox. Nowadays not one man in a hundred has ever

Digitized by Google

seen the disease and the public acquaintance with history is not so intimate or its imagination so realistic as to provide a motive equal to that which was furnished to our forefathers by everyday experience of the pestilence.

Democracy and autocracy have each their advantages as a form of government, and democracy in some countries adopts methods which even an autocrat might be tempted to envy. A free reading of Dr. Rauch's evidence before the Royal Commission may be given in illustration. Dr. Rauch was executive officer of the Illinois Board of Health. In his country there is no law of compulsory vaccination. Everybody is at liberty to remain unvaccinated if he pleases. In 1882 there was great risk of introduction of small-pox into the State of Illinois by immigrants. A meeting of the authorities of the different States was called and the National Board of Health was asked to require the vaccination of all immigrants. Pressure was brought to bear on the steamship companies and on the health officers at the ports. Very much was done in this way, and it was supplemented by the examination of all immigrants in course of transit by railway. Certificates were required of vaccination on board ship, and the arms of those thus certified were examined on board the trains during the railway journey. If the result was unsatisfactory the operation was again performed. In these ways many thousands were vaccinated. One day three Englishmen objected. Dr. Rauch was on the train. He explained to them that he wanted them vaccinated. They asked if vaccination was compulsory. "By no means," he said; "this is a free country." "Then we won't be vaccinated." "All right," he replied; "when we get to the border of our State I'll let you off the train." "But we don't want to get off." "Just so; but we won't have you in our State. We are a free people and will exercise our freedom in keeping you out." Then the three Englishmen got vaccinated—voluntarily, of course. In the same way the executive of a free people issued an order for the vaccination of all the children both in public and private schools. All the railway employés throughout the State were vaccinated or revaccinated and also the employés of all the manufacturing and mercantile establishments. In one mining town there was much small-pox and Dr. Rauch determined on general vaccination and revaccination. Here are question and answer as given before the Commission. Dr. Rauch says:—

"I issued an order to that effect, and it was enforced in an indirect way. Those who were vaccinated and revaccinated were permitted to leave their houses, but those who would not be vaccinated or revaccinated were compelled to remain inside of their houses. This is the way that I have acted in a number of instances and the result has been that of immediately stopping the epidemic." (Q.) "There is no law, is there, to compel an unvaccinated person to remain in his house? (A.) No; but that comes within the police jurisdiction of the State." (Q.) "You mean that it was absolutely compulsory that they should stay in the house unless they were vaccinated? (A.) Yes; that position has been maintained by the courts. If the local health authorities think it is necessary that persons should remain in their houses so as not to endanger the lives of others, they compel them to remain." (Q.) "And that applied to all the persons in a house where a case of small-pox had occurred? (A.) Yes; the result is simply this, that a person would rather be vaccinated than be compelled to remain in the house." (Q.) "Practically speaking, it operates as a compulsion sufficient to lead to the people being vaccinated? (A.) Yes."

Such are the proceedings of a great democracy. In Germany, where methods much more autocratic than ours are acknowledged to exist, there is an enormous saving of life and health by means of the stringent law of vaccination and revaccination which is in operation there. It is impossible, and would be unprofitable if it it were not impossible, to enter here on the never-ending question of where personal liberty ends and where the rights of society begin, or the similar question as to the relative responsibility of the parent and the State for the protection of the infantile community against disease. In this country a vaccination law such as that of Germany seems in the present state of public opinion impossible. The public have to be educated and they must pay for their education. In so far as they will accept no other schoolmaster than small-pox their education will be all the more costly, but the lesson, once learned, will be all the more thorough. The pity of it is that this schoolmaster accompanies his teaching by punishment and that the punishment so largely falls on helpless children. But it has always been the case, in matters physical, intellectual, and moral, that the sins of the fathers are visited on the children. It is our duty to make the visitation as light as possible, and mention of that duty brings me to the consideration of the relation of the medical profession to the prevention of small-pox in presence of the new law of vaccination. Shall we continue to do our utmost for the protection of the population against itself, or shall we stand aside and sulk because so-called compulsion has been temporarily abolished? Surely the question contains its own answer. It is mere truism to say that as medical practitioners we are bound to do our best for every patient, no matter how refractory and ungrateful he may be; that as health officers we are bound to do our best for the protection of the districts which have been committed to our charge, no matter what may be the attitude of the people or of the local authority; and that as a profession we are bound to persevere in our efforts to shield the nation from pestilence. The principles which underlie the oath of Hippocrates leave us no choice. If our patient be a man condemned to the scaffold we must try to cure him of the disease which threatens to rob justice of its victim; though we have reason to believe that the death of an individual would be a public boon we must endeavour to preserve his unworthy and mischievous life; and surely it is no less our duty to try to protect innocent children from the results of parental error and folly. The State, and not the profession, is responsible for the law, but we must continue to advise the State aright, and whatever be the law, even if there be no law, we must advise the individual aright.

Coming to closer quarters with this aspect of the subject let me refer briefly to certain specific points:—1. In the past a very large number of people though not doubting the efficacy of revaccination have yet contented themselves with a single operation. It is obvious that the risk of trusting to this—without renewal of the premium, as Dr. Bond would say—is all the greater according as the possibilities of infection increase. Now more than ever is it therefore the duty of medical men to advise revaccination as a supplement to primary vaccination. It should be pointed out to the individual that, independently of any law, he can practically defy small-pox so far as he is personally concerned and that under the new conditions there is all the greater need for his maintaining at its highest standard the protection which vaccination is capable of affording. To the guardians of adolescents this fact should be strongly brought home. 2. From this time forward every vaccination should be done as efficiently as possible. No medical man should ever again yield to a parental request to make only one small mark on a child's arm. Let the standard number of typical Jennerian vesicles be produced or let the parent go to the petty sessions and there obtain the relief which the new law allows. There can be no hardship in offering this choice and an incidental result of such a course will be to draw more and more clearly the already very clear contrast between the vaccinated and the unvaccinated in epidemics of small-pox. 3. I come last of all to the consideration of isolation as a means of the prevention of small-pox. A century ago Haygarth held that the atmospheric carrying power of variola did not exceed 18 in. and that isolation could quite well be accomplished and maintained within an ordinary dwelling house. For us isolation means the provision of hospitals, themselves properly isolated. In regard to this matter of hospitals it seems to me that we are in a curiously anomalous position. If vaccination and revaccination were universal we could practically do without small-pox hospitals, and it is a singular fact that one of the effects of national neglect of vaccination is that we have particularly to discuss hospital isolation regarding that particular zymotic disease for which hospitals would be essentially unnecessary, if only we would take full advantage of that preventive measure which is open to us in the case of small-pox as it is in no other malady.

But we must consider the question on practical lines and accept the fact that sanitary authorities cannot in the present condition of this country rely on vaccination and revaccination being so universal as to render small-pox hospitals unnecessary. That is a fact which the ratepayer must also accept. At the other extreme from a condition of universal vaccination and revaccination there would be an entire absence of vaccination and revacination. What part would hospitals play then? I am afraid that, at least as regards epidemic small-pox as distinguished from sporadic small-pox, they would be practically useless. Knowing what we do of the infective power of the epidemic disease it seems only too certain that any possible hospital accommodation would be utterly inadequate and that the infection would overleap all artificial bounds. Whether

Digitized by Google

at the close of an epidemic we would be in the position of the town of Chester in the last century is a question which at present is fortunately of only academic interest. But in that town, which, according to Haygarth, was a place of "almost incredible" healthiness, only some 7 per cent. of the population had never had small-pox. In the little village of Ware, under similar circumstances, Mr. Anthony Fage divided the population into three classes at the end of an epidemic in the year 1722. The total population was 2515. These he classifies thus: (*a*) those who "had the small-pox before," of whom there were 1601; (*b*) those who "had the small-pox this time," who numbered 612; while (*c*) the remaining 302 he describes under the suggestive heading, "to have the small-pox." For myself I would be inclined to hope that in spite of the high convectivity and infectivity of small-pox, and in spite of the doubts which have been cast on the value of hospital isolation in preventing the prevalence of so mild a disease as scarlet fever, which has no preventive means analogous to vaccination, yet the differences in the conditions of life between this century and the last would, even in the absence of vaccination, perhaps tend to prevent such experiences as those of Chester and Ware. But we cannot tell and we must fervently hope that we shall never have the opportunity of learning.

My point here is that if vaccination and revaccination were universal small-pox hospitals would be almost or altogether needless, and if vaccination and revaccination were entirely wanting such hospitals would be almost useless, at least against the epidemic disease. The nearer we approach to this last state the larger are our hospitals likely to grow and the more hopeless will it be to rely on them. In the intermediate condition—the condition in which we live—with vaccination and revaccination partly prevalent, hospital isolation is a measure of very great value and must be a routine part of the procedure with regard alike to the sporadic and the epidemic disease. Experience indicates that the administrative part of a small-pox hospital should be large and well-equipped and that around it there should be space for rapid extension of whatever ward accommodation is permanently provided. Needless to say, the word isolation means more than the removal of the patient. It means isolation of the poison by disinfection, or still better by destruction, of infected articles; it means not merely the removal of the patient but his very early removal, and this involves search for persons who have been exposed to infection, and constant watching of such persons during the possible incubation of the disease. All this belongs to the A.B.C. of preventive medicine and must be rigidly attended to. Yet it has to be admitted that though very valuable isolation with its concomitants is essentially a precarious protection. Even if we had a law making isolation more strongly compulsory than vaccination has ever been in this country, and even if there were to be no extension of that destruction of small-pox hospitals by infuriated mobs, of which there were two instances not very long ago in the West of England, yet isolation might fail at any moment. Under such a prophylaxis the individual has to depend not on himself but on other people. As I have said elsewhere his *cordon* of protection is a chain the measure of whose strength is its weakest link, and over not one link has he any sufficient control. Failure of parents to observe the symptoms of illness, failure to call in a medical man, failure of the medical man to diagnose small-pox, failure in promptitude of removal, inadequacy of hospital accommodation, insufficiency of disinfection of persons and things,—these are among the risks to which even a law of compulsory isolation would leave a man exposed. On the other hand, by means of vaccination and revaccination the individual himself is protected. He carries his protection with him wherever he goes and the father has control over the protection of himself and his children. All this, however, furnishes no excuse for refraining from utilising to the very utmost every measure supplementary and complementary to vaccination, no matter how uncertain such measures may be.

Finally, we must endeavour by every means in our power to educate the public, who choose our law-makers, in the very truth about vaccination. It is nearly twelve years since I first pleaded with the profession to undertake this education. The Jenner Society has within the last two or three years done yeoman service here, and more recently the British Medical Association has heartily aided in the work. May I suggest in conclusion that the Sanitary Institute might also now lend a hand?

Remarks
ON
MEDICAL PROGRESS.[1]

Being the Abstract of an Address delivered

BY L. A. WEATHERLY, M.D. ABERD.

GENTLEMEN,—"The *old* are ever learning much from the *new*; may not the *new* learn something from the *old*?" Some of you, possibly, imbued with the pessimism of Max Nordau, may shrug your shoulders at the very thought of the old being capable of either learning, appreciating, or acting upon any new ideas. You may agree with him that you cannot expect novel form of efforts from those stiff old organisms; that you cannot compel their trains of thought to leave the smooth and easy tracks and go bumping along over new and unbroken ground; that the old intellect has first to comprehend the new thought and secondly to conquer the tendency to formulate the idea in question in his old accustomed way; that it is to the minds of the old too much trouble to escape from the habits into which they have fallen and that even if they took this trouble that their central nervous system would be incapable of generating impulses of sufficient energy to enter untried paths. Yes, and to a certain extent you would have reason on your side for such mental argument. But surely the majority of you will believe with me that with the great and wonderful advance of science this class of "automaton" in medicine and surgery is the exception rather than the rule and that however old a medical man in active practice may be he is always willing to be enrolled among the learners and to glean new ideas and apply new methods of treatment for the benefit of his patients, though perhaps he may not be quite so enthusiastically confident as the young practitioner with regard to results.

On the other hand, some of the older school may ridicule the probability of the young men dreaming of learning anything from them and declare that they are far too satisfied with the rapid advance of science in their time to imagine for a moment that any of those who lived in the days before chloroform, antiseptic surgery, the use of the thermometer, the stethoscope, the ophthalmoscope, laryngoscope or the microscope could teach them anything which would in any way help them to do greater good to the patients entrusted to their care. Let us hope that such a young practitioner may be the exception rather than the rule and that if such a one exist he will exercise the intellect God has given him to reason out the evolution of science, and thus recognise that the grand wall of that science upon which to-day he stands had its foundations laid generations ago and that from anyone who has had anything to do with the setting of any one single stone of that structure something may always be learned.

As Kidd, in that most able work of his, "Social Evolution," so clearly points out: "The marvellous accomplishments of modern civilisation do not necessarily imply any extraordinary intellectual development in ourselves at all. They are not the colossal products of individual minds, but rather the results of small accumulations of knowledge, slowly and painfully made and added to by many minds through an indefinite number of generations in the past. In the fulness of time, when the ground has been slowly and laboriously prepared for it by a vast army of workers, the great idea fructifies and the discovery is made." And as Bellamy so well put it, "All that man produces to-day more than did his cave-dwelling ancestors he produces by virtue of the accumulated achievements, inventions, and improvements of the intervening generations." We are now rapidly approaching the close of a century which has seen a far greater advance in scientific evolution than any other in the world's history. In this marvellous advance medicine and surgery have shared and the Victorian era will ever be a striking landmark in the history of our profession and ever be remembered as a period in which science established her

[1] Presidential Address to the Bath and Bristol Branch of the British Medical Association, delivered on June 29th, 1898.

dominion and lent her powerful aid to the cause of humanity. The older writers on medicine, when physiology was yet in its infancy and thus an exact scientific knowledge of disease unattainable, sounded a warning note lest too much should be made of the principles of medicine to the detriment of its practice; and Sir Thomas Watson in his memorable lectures, from which the most scientific student of to-day may learn much, harped on the same string. If this were necessary in those days, how much more is such a danger signal of use in our own? Our present system of medical education is to my mind erring greatly on the side of devoting too much time to the science of our profession and too little to its art. At the recent Montreal meeting of the British Medical Association Mr. Christopher Heath spoke with no uncertain voice as to the tendency of modern surgical education, declaring that the teaching of the students was getting too much into the hands of professors who were anatomists but not surgeons, and that the practical surgeon has in the present day too little time with his pupils. It takes often three years for the student to get through his primary examination, leaving only two for the study of medicine and surgery; and he declares that the growing tendency of the non-medical teachers of collateral science to regard their particular subject as the one most essential for the medical student must be restrained and the preliminary period of medical study must be cleared of many obstructions if the student is to have the necessary time to devote to the thorough study of those strictly medical subjects which will fit him to be a sound practical physician or surgeon. Weighty words these and who can deny their truth?

There might have been a tendency in the old system of medical teaching to make the student too much a disciple of empiricism and to inculcate in him too great a reliance in what one might aptly call common sense; but could not the scientific book-reading student of to-day benefit much by a little smattering of rational empiricism and the education of common-sense reasoning? Clifford Allbutt recently said: "We must not allow ourselves to be blinded by the light of brilliant generalisation of the laboratory and the lecture room, helpful as such light may be to the value of these empirical rules which have been painfully gathered together in the trials and the errors of generations of men. At the same time it behoves us to continually submit our empirical laws to revision, bearing in mind always that empiricism is, after all, science without roots." Looking back to my student days I remember with true appreciation the value of my apprenticeship to my father. It was hard work to steal a few hours from the day, with the morning lectures and the work at the infirmary, to run off to Portishead to make up bottles of medicines, mix pills and fold powders; to listen to the talk of old women, with their "windy spasms"; to sympathise with old men, with their "coughing and a spitting"; to hear young anæmic girls describing what they called "populations of the heart and digestion of the stomach"; and to visit with my good old father some of his most anxious cases and hear from him an elucidation of the symptoms, the probable outcome of the disease, and the various reasons for his treatment; to watch how acute was his observation and to note how often before he had asked a single question he had come to a more or less definite opinion as to how his patient was. Irksome though I often thought those hurried journeys were, how frequently since that time have I realised the true value of the practical teachings I thus obtained? Yes, indeed, "science," as Oliver Wendell Holmes says, "is a first-rate piece of furniture for a man's upper chamber, if he has common sense on the ground floor; but if a man has not got plenty of good common sense the more science he has the worse for his patients."

The older practitioner sees day by day the instruments of precision growing more numerous, more exact, and more trustworthy. He realises that the themometer rationally used can tell him what his hand could not; he knows the value of the stethoscope and is fully aware of the possibility of more accurate diagnosis by the aid of the ophthalmoscope or the laryngoscope; he contemplates with befitting awe and wonderment the revelations made by the microscope; he bows with admiration before the successful workers in the science of bacteriology, and he pictures the possibilities which have been opened up by the knowledge of the relation of living germs to diseased processes and which at present cannot be calculated; he knows that while this new science is gathering round itself its sister sciences that it is already attacking the very strongholds of dire disease and he wonders how he in the days gone by could have been able to diagnose the cases he believes he did correctly appreciate or pull his patients through their many grievous bodily ailments successfully. Yet, while envying his younger brethren, while listening to their scientific papers and their minute diagnoses of obscure diseases, does he not feel that perhaps it would be well for them could they have some of the difficulties to encounter which fell to his lot before science had so asserted her sway? The Italian painters say, "The eye can only see what it has learned to see." May not we say the same of all the senses? And had not the older men of our profession to depend almost entirely upon their organs of sense, not having our present grand array of diagnostic instrumental armamentaria? And how much can the eye see if properly trained? As Dr. Fothergill wrote: "The youthful gaze may see nothing, though the eye is young and the vision keen, where to the duller eye of advanced life the face may be a written page whose characters are both familiar and distinct." What the trained medical eye can see forms the great portion of that individual experience so valuable and yet so absolutely untransferable.

Professor Laycock always insisted on what he termed carefully cultivated physiognomical diagnosis and there can be no doubt that our older medical brethren were obliged to cultivate this to a very great extent. Might not the younger members of the profession with advantage do the same? By it important hints are given for physical investigation and from it are often furnished most valuable suggestions as to treatment to be adopted. To use the words of the Professor: "Study well the physiognomy of disease—that is to say, all those characteristics in the patient that reach the unaided senses and which are associated with morbid states; whether they be sounds or odours, or visible and tangible modifications of form, complexion, expression, and modes of functional activity; taking cognisance of *minute* modifications as well as of the more obvious, for they are only minute in a popular sense. Technically a shade of tint of the skin; a quickly passing change in the expression, an almost imperceptible modification in the breathing or mode of speaking; the ring of a cough; a local, and in itself trivial, development of a capillary network; a slight twitching of a muscle, or a tremor, may be as clearly significant of structural disease as the most characteristic and undoubted physical sign." The love of scientific detail and ascertained facts often causes the highly educated medical man of to-day to lose sight of the more general characters of constitutional disturbance and consequently handicaps him most seriously both in the prognosis and the treatment of his patient's case. Professor Erichsen not so long ago maintained that at the present time we are apt to pay too strict attention to physical diagnosis, and by so doing the educated student of to-day is making himself actually less useful to the sick man than his less perfectly trained predecessor, who by reason of his more general observation was often a superior antagonist to disease.

I well remember my first case of pneumonia when I started practice and how I hurried home to tell my father with a certain amount of pride what I considered a more or less definite piece of physical diagnosis. My father paid little attention to my recounting the extent of dulness and the characters of the respiratory sounds and more or less abruptly broke in with the simple question, "What are his general symptoms?" and then started a cross-examination as to his general expression, colour of skin, clearness of mind, amount of sleep and length of uninterrupted sleep, how he had taken his nourishment, the amount of urine he had passed and its condition, and on hearing my answers gave me a prognosis diametrically opposite to the one which my physical diagnosis had led me to believe. And he was right. He taught me a lesson which has stood me in good stead.

The druggists of our time have done much for us by their elegant pharmacy to make the administration of drugs far more pleasant for our patients; they are for ever introducing to our notice new remedies, novel preparations of old medicine; they are putting their pills and their tabloids into neatly labelled bottles with the dose to be given and the complaints to be cured by them writ large; they are sending out pamphlets broadcast, with description of diseases which can be quickly defeated by this or that new drug, with some grand sounding Latin or Greek name; and the medical practitioner is getting constant gifts of useful diaries with long lists of therapeutic agents as manufactured by this firm or that, and maybe he is inveighed into carrying about in his

Digitized by Google

waistcoat pocket a leather case of little flasks containing different coloured pilules, which he is able to prescribe instanter as occasion arises, yellow for the liver, green for the chest, blue for the stomach, and pink—well, we know by our daily paper what they are for. Is this all an unmixed blessing? I do not deny that in many instances the modern tendency of pocket prescribing may be useful, but is it not too much putting our patients into the hands of the advertising druggist? and is it not getting us out of that art of prescribing, an art which can only be learnt by practical experience in the surgery of the general practitioner or behind the dispensing counter?

And with all these new drugs which are constantly being brought to our notice, are we not perhaps losing sight of the wonderful results the practitioner of bygone days had with some of the old-fashioned medicines simply because perhaps we are not yet able to explain their action and therefore think that they should be rejected? The alteratives which the older practitioner found so useful and prescribed with such good results are, in my opinion, too much neglected in the present day. That grand old drug, calomel, has been allowed by the younger generation to take too much of a back seat in favour of more fashionable remedies. My father never went his rounds without having in his pocket a little box of pilula hydrargyri subchloridi, gr. iii., and many an illness was cut short or limited by the early administration of what I remember some of his club patients called "the old doctor's little scavengers."

Could we wake from his everlasting sleep in this world a surgeon of sixty years ago and place him in one of our modern operating theatres how he would rub his eyes to stare with utter amazement at the daring deeds of the modern surgeon. He would see the patient brought in already unconscious of what was about to be done; he would note the scrupulous cleanliness which antiseptic surgery has taught us in all the surroundings of the room, the appliances of the operating surgeon and his assistant; he would, perhaps, see the abdomen opened and its contents handled with the most perfect confidence; and this or that operation, never dreamt of in his day as being even possible without instant death, brought to a successful termination. And wonderment would be justifiable. Can we to-day believe, as Dr. Playfair recently reminded us, that it was only a comparatively short time ago that the benches of the Royal Medical and Chirurgical Society rang with excited cries of "Down with the belly-rippers!" when Spencer Wells had the temerity to bring before it a paper advocating ovariotomy. All honour, then, to the discoverer of anæsthetics and the pioneer of aseptic surgery. By their work what has humanity gained? Surely, if a successful general had with his army killed as many lives as these men have saved from the grim hand of death a grateful country would have showered upon him honours galore and wealth beyond the dreams of avarice.

And yet with all the marvellous results of modern surgery, with all the quiet confidence with which the operator of to-day takes his knife in hand, with all the truism that anatomically there is nothing impossible to the surgeon and that physiology alone steps in and cries, "Halt, enough," may not the young surgeon learn something from his older brethren? Is he not perhaps a little too much given to elaboration and detail in his operations, making them too long and increasing the chance of shock, and might he not with advantage educate himself in that celerity and dexterity which was absolutely essential to the surgeon who had to deal with his hapless patients before the blessings of anæsthetics had started a new era in this branch of our profession? Is not the young surgeon perhaps a little too prone to use his knife as a means of diagnosis without giving his powers of observation a chance of arriving at a right conclusion, and may not the conservatism of his older brethren be a useful check in some cases to his ardent desire to do what he may think is the only thing for his patient?

Only a few weeks ago Mr. F. Treves read a paper before the Medical Society of London on abdominal section as a remedial measure and in conclusion spoke of the exploratory incision as follows: "That this simple procedure has been of enormous value no one will doubt. That it has been the means of saving many a life has been amply demonstrated. That it has enabled a correct diagnosis to be made and a logical treatment to be carried out in hundreds of obscure cases needs not to be insisted on; but there must arise in the minds of many the question whether the exploratory incision, infinite as its value may be, is an entirely unmixed blessing. I notice that there are indications which tend to allow this ready measure to replace the admirable labour of clinical observation. The incision is so simple, the collecting and arranging and judging of clinical evidence is so difficult and tedious. With a scalpel in the hand the patient, searching examination of the abdomen as practised in the old days is no longer needed and it is a question whether the education of those who wish to become acute clinical observers has not suffered a little thereby." The caustic stick and speculum era will long be laughed at by the younger generation who know now how little of the "ulcer of the cervix" there existed, and the age of "flexions" and the innumerable kinds of pessaries which the practitioner of the fifties, sixties, and seventies carried about with him has more or less passed away. Yet these instruments if properly applied may give comfort to many women and possibly the surgeon of to-day is a little too prone to use his knife and his needle when in many cases he might by the proper application of a suitable pessary do more for his patient. Wholesale acceptation of practice which has been proved to be in many cases opposed to scientific teaching becomes bigotry of the worst order, but may not wholesale condemnation be equally savouring of that fault? We are, I am afraid, while preventing the pendulum swinging too far in one direction, often allowing it too much play in the other.

In the successful practice of midwifery asepticism is playing an important part and the death-rate of women in childbirth when attended by duly qualified practitioners is gradually but surely lessening. We realise now how absolutely necessary is the most perfect cleanliness and we practice it with grand results, and yet in these days of hurry and scurry, of restless desire to do everything in record time, is not the word of warning spoken by Dr. Sinclair to the young practitioner in midwifery a useful one? With the use of anæsthetics, with the knowledge that slight injuries can now be so quickly and surely treated with hope of rapid recovery, is he not too prone to rush to his long forceps for assistance? No doubt, with time precious, with the anxious father longing for the news of his wife's safety and the advent of his first-born, the young medical man is often tempted to assist nature when nature is really crying out for patience and for time. With shirt sleeves turned up, with long forceps in hand, it may be a satisfaction to him to whisper through the keyhole to the impatient and anxious father the news that the trouble will soon be over, but it may not be quite so gratifying if some moments later he has, while congratulating the parent on the arrival of a bouncing "he" or "she," to commiserate with him on the possession of a wife with a ruptured perineum. Patience is what the older practitioners have had to exercise and it is patience that the young medico should try his utmost to inculcate.

These, then, are a few thoughts hastily, and I fear very clumsily, thrown together; and if I have made too many quotations, if I have mentioned too many names of men whose worth and work are known to you, I have done so simply to prove that these thoughts have some substance in fact and do not result from any egoism, but owe rather their creation to the practical school in which, however imperfectly, I tried my best to learn my profession. Much more might be said of the useful lessons to be learned by all from the study of the practices of the past. It is a subject to my mind replete with interest and one which would serve admirably for debate. I only wish it could have to-day been dealt with by one more capable than myself. Dear old "Johnnie Toole" once lunched with the late Lord Tennyson and the late Mr. Gladstone and he told a friend that the conversation of those great men had been of such a highly intellectual order that when he left the house he had to catch hold of the first policeman he met and have a chat in order to bring his mind down to the level of everyday life. I fear to-day the converse will happen and that you are already longing for the close of this trivial address in order that you may link your arm in that of some scientific brother and get quickly rid of the taste of my common-place maxims. And yet I venture to think that if what I have feebly brought before your notice is true its common-place hall-mark need not detract from its utility. To those who have long since believed in these maxims no apology is needed, whilst to any who may be too self-satisfied, too cocksure with their scientific teaching and knowledge of to-day, it may start in their highly intellectual and deep-thinking minds the

possibility that, after all, in these days of rapid evolution it does not do to cast aside as worthless the lessons taught us in medicine and surgery by our fathers and forefathers, who worked honestly and bravely in the study and practice of our grand and humane profession.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.[1]

BY A. H. WENTWORTH, M.D.,

ASSISTANT IN DISEASES OF CHILDREN AND IN PATHOLOGY IN THE HARVARD MEDICAL SCHOOL; ASSISTANT PHYSICIAN TO THE CHILDREN'S HOSPITAL, AND SENIOR ASSISTANT PHYSICIAN TO THE INFANTS' HOSPITAL, BOSTON.

(From the Sears' Pathological Laboratory of the Harvard Medical School.)

THE earliest epidemic of cerebro-spinal meningitis which has been reported occurred in Geneva in 1805 and was described by Viesseaux. In 1806 the disease occurred in epidemic form in Massachusetts and was described by a committee appointed for the purpose by the Massachusetts Medical Society in 1809. Since then epidemics have been described in various parts of Europe and America.

With regard to the etiology, in 1887 Weichselbaum described a diplococcus which be obtained at the necropsies of six cases of epidemic cerebro-spinal meningitis. This organism, which very closely resembles the gonococcus morphologically, he found in the protoplasm of the pus corpuscles and to a limited extent free in the inflammatory exudation in the meninges. The chief difference between it and the gonococcus is that it can be grown on ordinary culture media. The best culture medium is Löffler's blood-serum. Weichselbaum called this organism the diplococcus intracellularis meningitidis. During the last three years the diplococcus intracellularis has been found repeatedly by many other observers both in epidemic and sporadic cases of the disease. As a rule inoculation experiments have been unsuccessful. Injections of pure cultures into the pleural and peritoneal cavities of animals have produced sero-fibrinous inflammations and death in some cases. Meningitis has been produced in goats, in a few instances, by injections of cultures of the diplococcus into the spinal canal, and the organism has been recovered from the exudation in the meninges. The organism appears to be very susceptible to outside influences and it is often difficult to obtain more than a few colonies from the exudation in the meninges at the necropsy. Better results are obtained when cultures are made from the spinal fluid obtained during life by means of lumbar puncture. On culture media the organism rapidly loses its power of growth, and to maintain this power it is necessary to make fresh cultures every day. There have been no cases reported of general blood infection by this organism.

As to predisposing causes, there appears to be little or no influence exercised upon the spread of the disease by bad hygienic surroundings. Most epidemics have occurred in the winter and spring and sporadic cases have been observed throughout the year. A very large proportion of all the cases have occurred between the ages of two and thirty years. Both sexes appear to be equally susceptible to the infection.

Most observers are agreed that the disease is but slightly, if at all, contagious. The way in which infection takes place is not known. The organism has been found in the nose in some cases. The period of incubation has not been determined.

With regard to its pathology, the lesions consist of an inflammation of the pia-arachnoid. The exudation is confined in the meshes of the pia; none is found on the surface of the arachnoid. In the most acute cases the exudation is slight in amount and purulent. In acute cases of longer duration there is more fibrin in the exudation. The pus cells are contained in the distended meshes of the pia. Large cells derived from proliferation of the cells of the lymph spaces and from the connective tissue corpuscles appear. These cells are phagocytic and often enclose numbers of the exudation cells within them. In the very chronic cases the membranes are thickened. The exudation is slight in amount and is marked only by circumscribed whitish foci. The cells in these foci are degenerated and do not stain well. The ventricles are always distended. The ependyma is softened and frequently ragged. The fluid is cloudy and a small mass of fibrin or pus is always found in the posterior cornua of the lateral ventricles if the body has lain on the back. The changes in the brain consist of softening and infiltration of the cortex with pus cells, which extend in from the meninges, and of foci of softening in the interior of the brain. There is also some proliferation of the neuroglia cells of the cortex. The exudation extends along the cranial nerves. The nerves most affected are the second, fifth, and eighth pairs. The meninges of the cord are always affected and the exudation is found chiefly in the meninges of the lumbar cord over the posterior surface. The inflammation extends along the spinal nerves to the spinal ganglia. The changes in the interior of the cord are not so marked as in the brain. Degenerations are found in the cranial nerves and in the spinal nerve roots.

(The above description is a brief abstract of the pathological anatomy of the disease as given by Councilman, Mallory, and Wright, "Epidemic Cerebro-Spinal Meningitis," &c. Report of the Massachusetts State Board of Health, 1898.)

In considering epidemic cerebro-spinal meningitis it is very important to remember that the frequent variations which occur in this disease depend not so much upon the presence or absence of certain symptoms as upon differences in their intensity and the period at which they occur. Strümpell has said that perhaps the most striking feature in the disease is the constant variation in the intensity of the nervous phenomena, not only from day to day, but oftentimes in the same day. Certain symptoms which are almost constant in their occurrence are headache, pain in the neck, retraction or rigidity of the head, pain in the spine, and some degree of mental disturbance. Other symptoms which are not so constant but which occur very frequently are vomiting, hyperæsthesia, herpes, changes in the pupils, and conjunctivitis. The moderate and irregular type of fever is very characteristic and forms a striking contrast to the severe nervous symptoms. To obtain a clear impression of the disease it is necessary to consider it in its entirety, the onset, the sequence of symptoms and the variations in their intensity, the peculiar temperature and pulse, and the course of the disease. The picture thus presented is characteristic and in a large number of cases is unlike any other disease. In order to give an adequate and at the same time a clear impression of the variations in the symptoms the latter will be described in detail and the different types of the disease will be briefly alluded to afterward. These types have been classified clinically as foudroyant, acute, intermittent, chronic, mild, and aborted.

With regard to the onset, epidemic cerebro-spinal meningitis almost always begins suddenly. A number of observers have reported cases in which prodromal symptoms occurred and lasted for several days, in some cases for two weeks. These symptoms consisted of malaise, pains in the extremities, and headache. From the character and distribution of the lesions in the meninges, and from the severity and rapidity with which the symptoms develop in most cases, it is not improbable that in some of these cases at least the apparent prodromal symptoms were merely coincidences.

The earliest symptoms are, as a rule, fever and severe headache. In quite a large proportion of cases vomiting is one of the earliest manifestations, especially in children. In a small proportion of the adult cases the disease begins with a chill, which may be repeated. Convulsions are quite uncommon in adults, but in children they are by no means infrequent as one of the initial symptoms. These symptoms will be considered in detail. There is no definite and constant relation between the height of the temperature and the severity of the other symptoms. This is one of the most characteristic peculiarities of the disease. Very often the temperature is moderately elevated at the onset and may remain so for several days or throughout the disease in acute cases. If a four-hour chart is kept remissions will be found to occur, oftentimes of several degrees. Not infrequently the initial fever is very slight, although the nervous symptoms which rapidly supervene may be very severe; these cases usually occur in adults. Quite a number of cases have been reported in which there were severe headache, pain in the neck and

[1] A paper read at the annual meeting of the Massachusetts Medical Society, June 7th, 1898.

Digitized by Google

spine, and mental disturbance, and the temperature remained normal for several days in the early part of the disease. In children as a rule the temperature at the onset is higher than in adults, not uncommonly 104°F. It shows the same tendency to remit as in adults. It is quite rare to find only a slight elevation of temperature in children in the initial stage. After the first few days there are usually marked irregularities in the height of the temperature from day to day. It is rarely more than moderately elevated later in the disease, and very often the exacerbations and remissions occur independently of the other symptoms. Occasionally the temperature assumes an intermittent character for several days. There may be no parallelism between the fever and the other symptoms at these times. In the chronic form of the disease, after three or four weeks, the temperature is very apt to be normal or subnormal, with now and then slight elevations. The nervous symptoms, however, continue with exacerbations and remissions. Ante-mortem rises in temperature are not uncommon, but many patients die with little or no fever. The above description is by no means a complete one of the many variations which occur in the temperature, but enough has been said to indicate how little relation exists between the fever and the nervous symptoms in many cases.

The disease almost always begins with headache. It is often very severe and persistent and in some cases it is the most marked symptom for several days. It is rarely absent. Vomiting is frequently one of the initial symptoms, although it may not appear for a day or two. It may persist for several days, but usually is of short duration. In chronic cases it is apt to recur at intervals and may become a dangerous symptom. Rigors may be one of the initial symptoms and may occur later with exacerbations of the disease. It is not so constant as the other symptoms and is not common in children. Convulsions are quite uncommon in adults but are by no means infrequent in children at the onset of the disease. The occurrence of convulsions is by no means an index of the severity of the disease. They may occur in some cases which are rapidly fatal, but they also occur in cases in which the disease pursues the usual course. Convulsions are rare late in the disease under any circumstances.

As to the later symptoms retraction of the head and pain and tenderness in the neck are constant and usually appear early. It is somewhat exceptional for them to be delayed for several days. A very marked variation is observed in the intensity of the pain and tenderness, not only in different cases, but in the same case from day to day. There is the same pronounced tendency to exacerbation and remission which takes place in the other nervous symptoms. In many cases these symptoms are but moderately severe at any time; in others they are so severe as to cause opisthotonos for a time. There appears to be no constant relation between the quantity, character, and location of the exudation in the meninges and the degree of pain and retraction. This has been demonstrated at necropsies and I have examined spinal fluid which contained many organisms and in which a purulent sediment formed in the bottom of the test-tube in a number of cases which had but moderate pain or tenderness in the neck and only a mild degree of stupor throughout the disease. In other cases the above symptoms were very much more severe and the fluid was only moderately turbid. In some patients the symptoms of spinal irritation are more pronounced than the cerebral.

Some degree of mental disturbance always occurs in the course of the disease and varies from apathy to unconsciousness. This is one of the early symptoms in most cases and usually occurs within a day or two of the onset, in many cases in the first day. In some of the rapidly fatal cases the patient becomes comatose within a few hours. In some severe acute cases there may be temporary unconsciousness early in the disease and subsequently these patients may show varying degrees of apathy or stupor. Often the degree of mental disturbance is milder and varies from apathy to stupor. Delirium is not uncommon and may assume at times a violent character. As the disease continues marked changes occur in the mental condition at short intervals, frequently in the same day.

Hyperæsthesia is not a constant symptom, but is nevertheless of frequent occurrence. It usually appears at an early stage of the disease and may occur later, when there are exacerbations. It varies from moderate general tenderness to extreme sensitiveness.

Herpes occurs very frequently. The lesions are usually confined to the lips and face. Rarely they have been found on the neck and shoulders. The herpetic efflorescence usually appears between the third and sixth days and is not an index of the severity of the meningitis. Other efflorescences are not so common, although roseola has been observed and petechiæ and ecchymoses occur at times. The latter are oftenest seen in severe cases. It would seem from the literature as if efflorescences occurred more frequently in the earlier epidemics than at the present time. It is not impossible that this may be due to greater accuracy in diagnosis at the present time.

Dilatation of the pupils and incomplete reaction to light occur quite frequently, oftentimes early in the disease. These conditions are not necessarily associated with lesions of the eyes and often show the same tendency to variations as the other nervous symptoms. At times the pupils are unequal. Nystagmus is not an uncommon symptom. Strabismus occurs frequently. It may be either convergent or divergent and appears to have no connexion with the severity of the disease. The condition is almost always a temporary one and both varieties of strabismus may occur in the same patient.

Paralyses are not so common as the other nervous symptoms. They may occur early in the disease and usually affect the extremities and at times the face. Ptosis is seen in some cases. The paralyses are not often complete and are very apt to be temporary, sometimes only lasting for a few days. Patients who have had paralytic symptoms and who recover from the disease rarely show evidences of paralysis at the time when they are discharged from observation. It is uncertain whether paralyses recur later in these individuals. General cerebral and spinal symptoms are much more common than localised ones. The reflexes vary a great deal. The deep reflexes may be increased, absent, or normal. There seems to be no connexion between the reflexes and the severity of the meningitis.

Emaciation is a constant symptom if the disease lasts longer than a week or two. In chronic cases the patients are always extremely emaciated; in some cases they are reduced literally to skin and bones. Constipation is a very common symptom and often requires periodic treatment to relieve it. Retracted abdomen and the *tache cérébrale* are present in many cases, especially in children, but are of no diagnostic importance. The urine often contains a slight trace of albumin and occasionally a few hyaline casts. Retention of urine is not uncommon in adults, but is much less so in children.

In adults there is usually a striking contrast between the rapidity of the pulse and the other symptoms. In a large proportion of cases the pulse is slower than normal in spite of the elevation of temperature and severe nervous symptoms. This symptom is not often observed in children, in whom the pulse is often very rapid. In both adults and children there is a marked variability in the pulse-rate at different times in the day. The variations may exceed twenty or thirty pulse beats in a minute. In cases which terminate fatally there is usually a marked increase in the pulse-rate. There is usually nothing striking about the respiration. It may be somewhat increased in rate, but is often within normal limits unless there is some complication in the lungs. The area of splenic dulness is rarely more than slightly increased and the spleen is not often palpable.

Conjunctivitis is such a constant symptom that it can hardly be considered a complication. It usually occurs within a few days of the onset. Severe lesions of the eyes are not rare. They may be caused by degeneration of the nerves or by extension of the inflammation from the meninges into the retina and choroid. Of these severe lesions optic neuritis occurs most frequently and may be followed by atrophy of the disc. The inflammation of the retina may be mild or severe and in some cases produces partial or total blindness. Some cases in which the lesions are severe recover their sight later. A few cases have been observed in which moderately good vision has been restored after some degree of atrophy of the discs. Irido-choroiditis occurs more rarely. Councilman claims that it is caused by direct extension of the inflammation from the meninges and is not metastatic in this form of meningitis. Optic neuritis may occur without showing external evidence of its presence and without much disturbance of vision.

Lesions of the auditory nerves and internal ears are quite common and are caused by extension of the inflammation from the meninges along the auditory nerves to the labyrinth. These lesions are severe and often cause permanent

Digitized by Google

and complete deafness. Acute suppurative inflammation of the middle ear occurs quite frequently. It may be caused by direct extension from the brain, or in some cases may be produced by other pathogenic organisms which reach the ears by way of the Eustachian tubes.

There is much variation in the frequency of joint complications in different epidemics. In the epidemic in Nauplia reported by Kotsonopolus this complication occurred in almost all cases. In most epidemics the number was limited. The symptoms consist of acute swelling, redness, and pain, which subside after a few days. The knees, ankles, wrists, and elbows are the joints most often involved. In many cases only one joint is affected. But little is known of the nature of the lesions. Still claims that the disease is not in the joints, but is in the sheath of the tendons in the neighbourhood of the joints. He has found the diplococcus intracellularis in one case.

Complications in the lungs do not occur so frequently as in the eyes and ears. Focal pneumonias are not uncommon and are caused in some cases by the diplococcus intracellularis. In others they are due to a mixed infection by the pyogenic organisms. Croupous pneumonia caused by the pneumococcus is much rarer than focal pneumonia. Lesions of the heart are very uncommon. A few cases of acute endocarditis have been reported in which the cause was not determined. Nephritis is a very rare complication. I have found no record in the literature of cases of septicæmia caused by the diplococcus intracellularis.

Foudroyant cases are not very common. They appear to have been much more frequent in earlier epidemics. These cases prove fatal in a few hours—usually from 12 to 36. The onset is sudden and severe, beginning with fever, headache and vomiting, and at times with convulsions, more especially in children. The initial symptoms are rapidly followed by stupor and unconsciousness. The temperature may be high; the skin becomes grey and there are usually multiple small hæmorrhages in the skin of the body and extremities. The spinal symptoms may not develop and the clinical picture may resemble septicæmia more than meningitis.

Acute cases run their course in from two days to two weeks. Although the general type of these cases is similar there are many individual variations. In some cases almost all of the symptoms which have been enumerated may occur; in other cases several of them may be absent. The cases differ also in the sequence and time of occurrence of some of the symptoms. There are also marked differences in the intensity of certain symptoms. Quite a large proportion of the cases show characteristic remissions and exacerbations in the severity of the symptoms at short intervals, but there still remains quite a number of cases in which exacerbations and remissions do not occur; these patients continue in about the same condition for a varying number of days and then the symptoms either gradually subside and recovery takes place or severe symptoms intervene and prove fatal, or a chronic form of the disease develops.

Intermittent cases differ from acute cases in having one or several acute exacerbations with intervals of several days during which the temperature may be normal or more or less elevated, but the cerebral and spinal symptoms disappear and the patient appears to be convalescing. This is followed by a return of the acute symptoms, which may last for several days as before. Sometimes two or more of these exacerbations occur. The intervals between the acute attacks rarely exceed a few days, but several cases have been reported in which the intervals lasted for from two to three weeks. Some cases die during an acute exacerbation, others recover after one or more attacks, and in some cases a chronic form of the disease develops which may terminate fatally or in recovery. Emaciation is a marked symptom in the intermittent cases.

Chronic cases begin with the usual acute onset and succession of acute symptoms. After a varying number of days the temperature subsides and may remain normal, subnormal, or slightly elevated for weeks. The cerebral and spinal symptoms persist with varying degrees of severity. Sometimes the patients show little or no evidence of meningitis for several days and then the symptoms recur. The increase in severity of the symptoms may be accompanied by rises in temperature, although the latter often remains normal or subnormal. At times elevations of temperature occur without any marked symptoms. The symptoms are generally more or less mental disturbances, headache, pain and tenderness in the neck and spine and retraction of the head. Emaciation is very marked. The patients usually take but little food and gradually grow weaker. At times there is temporary improvement in the cases which end fatally. In the cases which recover there is usually a gradual cessation of the symptoms. When the disease ends fatally death usually takes place suddenly and quietly. When lesions of the eyes and ears occur in chronic cases they do so in the early stage of the disease at a time when the acute inflammation is present in the meninges.

Mild cases may begin with the same sudden onset as the other varieties, so that in the beginning it may be impossible to determine that the disease is going to pursue a mild course. In general, however, the symptoms are milder and subside after a varying number of days.

Aborted cases are described by Strümpell as beginning with sudden and severe symptoms which rapidly subside after a day or two.

Many of the symptoms of epidemic cerebro-spinal meningitis are so constant and characteristic that the diagnosis is not difficult in a large proportion of the typical cases if one takes into consideration the whole picture of the disease: the sudden onset, the constant occurrence of cerebral and spinal symptoms early in the disease, the tendency to variation in the intensity of the nervous symptoms from day to day, the absence of correllation between the nervous symptoms and the temperature and pulse, the eye and ear complications, and the frequent occurrence of herpes. Chronic cases when seen late in the disease are the most difficult to diagnosticate and the diagnosis may depend upon obtaining an accurate history of the onset and earlier symptoms. In several instances a diagnosis of chronic cerebro-spinal meningitis has been made by means of lumbar puncture when all other methods of diagnosis had failed. The diagnosis may be difficult or impossible in the early stage of the disease and in mild cases without the aid of lumbar puncture. Furthermore, it is important, as Councilman has pointed out, to obtain all the information possible about the different varieties of meningitis with regard to their etiology, frequency of occurrence, and termination. This can only be accomplished by means of an accurate method of diagnosis, such as is furnished by lumbar puncture.

When symptoms of any variety of active meningitis are present it is very rare to obtain spinal fluid in which, after standing for several hours, one cannot find fibrin or cells microscopically. In many cases it is even possible to find slight evidence of inflammatory exudation when the patients are convalescent. This method of examination fails at times, as do all methods of examination, but I believe that it does so less frequently than any other clinical means of diagnosis, such as the examination of the sputum, urine, and blood, Widal's serum test, &c. This belief is based upon work done by me during the past three years and includes upwards of 200 punctures. The technique of obtaining and examining the cultures and of making the microscopic examinations of the fluid have been systematically and carefully performed during this period. The results obtained warrant conceding a higher place to this than to other methods of clinical diagnosis. There are fewer sources of error to modify the accuracy of this test than in the others. The spinal fluid either contains cells and fibrin which denote inflammation of the meninges or else the fluid is perfectly clear and contains neither cellular elements nor fibrin. In the other tests various diseases or pathological conditions may give similar results, or at least so modify the results as to make a positive diagnosis impossible in many cases, in addition to the negative results which are obtained in a relatively large number of cases.

It is not necessary to describe again the technique of the operation. It may be well, however, to allude to some of the sources of error. In some cases one fails to obtain any fluid. This may be due to several causes: the needle may not enter the spinal canal; the needle may be in the spinal canal but outside the dura mater—that is, between the dura mater and the wall of the canal; the needle may be in the sub-arachnoid space but may be occluded by a blood-clot or a small particle of skin; the needle may be in the sub-arachnoid space but its point may be buried in the dura mater on the opposite side, or the lumen of the needle may be obstructed by resting against one of the nerves. To control these sources of error it is necessary to have a wire which is large enough to fill completely the lumen of the needle. This wire should of course be sterile. If the wire is much smaller than the lumen it is

Digitized by Google

likely to pass through, or to one side of, an obstruction in the lumen and may not remove it. If the lumen is shown to be clear by passing a wire and a slight withdrawal of the needle does not cause the fluid to flow then in most cases it will be found that the needle has not penetrated the dura mater but is outside of it. To obviate this it is necessary to withdraw it for a distance not sufficient for it to leave the spinal canal and then to thrust again, directing the point more towards the median line. If these various procedures be performed one will rarely fail to obtain fluid.

The chief source of error in the examination of the fluid is a reliance upon the macroscopic appearances of the fluid alone, although in many cases they are characteristic. A very slight admixture of blood will render the fluid cloudy. The quantity of blood may not exceed the fractional part of a drop and still will produce a diffuse cloudiness. In most cases even this small quantity imparts a slight tinge of yellow to the fluid and after the fluid has settled the blood collects in a small drop at the bottom of the test-tube. When such a small quantity of blood as this is present there is no formation of fibrin, and it is usually easy to exclude the presence of inflammatory exudation microscopically from the absence of fibrin and leucocytes. If, therefore, blood appears at the end of the needle it is necessary to allow a sufficient quantity of the fluid to escape until the latter appears to be clear. It seldom is necessary to allow more than one cubic centimetre to escape in this way. The fluid after this is done is still very likely to contain a trace of blood, but not enough to interfere with the later examination. If the spinal fluid does not become clearer at once it is generally because the point of the needle is scratching the membranes, and it is necessary to withdraw it a little or to slightly alter its position. If considerable blood is mixed with the fluid there will be a formation of fibrin later. The fluid may be slightly cloudy from particles of dust which may be in the tube or come from the cotton at the upper part. The microscopic examination readily detects this, even if one is not certain from the macroscopic appearances. Not infrequently larger white particles of epidermis are present in the fluid; they should never be mistaken for the very fine diffuse cloudiness due to cells. Sometimes a faint diffuse cloudiness may be caused by the presence of bacteria and their products in cases of septicæmia. In these cases the cultures will show the organisms and there will be no evidences of inflammatory exudation microscopically.

The technique of the microscopic and bacteriological examinations of the spinal fluid are important. After it has stood for some time there is a formation of fibrin in cases in which the fluid is slightly or moderately turbid and a precipitation of pus when the exudation is more purulent. In some instances the quantity of the fibrin is small and may adhere to the bottom of the test-tube. The supernatant fluid is left perfectly clear under these circumstances, and unless the fluid is carefully examined this sediment may be overlooked. It is necessary in all such cases to scrape the bottom of the test-tube with the platinum wire in order to dislodge the fibrin. If the test-tube has been allowed to remain in a slanting position and only a small quantity of exudation is present it adheres to the side and may not be noticed. This may account for some of the negative results obtained in cases of meningitis, in which the fluid was said to have been perfectly clear like normal fluid. In many cases even when the quantity of fibrin is small it adheres to the bottom of the tube by its lower end and the remainder floats in the fluid like a web. The fibrin contains the cells in its meshes. Cover-glass preparations of the fibrin should be made, dried by passing them through the flame of a Bunsen burner, or alcohol lamp, and stained. Löffler's methylene blue gives the best results. By means of this stain the nuclei of the cells are very clearly defined so that the character of the exudation can readily be detected. In addition it stains any organisms which may be present. To differentiate the diplococcus intracellularis from other organisms a second cover-glass preparation should be stained by Gram's method. (By this method the intracellular diplococcus becomes decolourised.) Cover-glass preparations may also be stained for tubercle bacilli by appropriate methods of staining, but the organisms are so few in number that more accurate results are obtained by inoculating guinea-pigs with the spinal fluid. In cases of tuberculous meningitis this produces tuberculosis in the guinea-pig in from four to six weeks.

The cells in the spinal fluid from cases of epidemic cerebro-spinal meningitis are chiefly polymorpho-nuclear leucocytes—"pus-corpuscles." In addition there are found a varying number of small mononuclear cells—"lymphoid cells"—and large phagocytic endothelial cells. These latter cells are very large and have large oval or round nuclei. In the protoplasm of some of them one finds leucocytes, blood-corpuscles and particles of cell detritus. In the protoplasm of some of the "pus corpuscles" one usually finds one or more diplococci. Sometimes a leucocyte contains large numbers of them. In this variety of meningitis the majority of the organisms are contained within the "pus corpuscles" and are found only in limited numbers outside of the cells.

Towards the end of the disease in acute cases which terminate in recovery the "pus corpuscles" show evidences of degeneration. The nuclei do not stain sharply and many of the cells appear to be disintegrated. This appearance indicates that the acute inflammatory process has subsided, at least for a time, and may have some prognostic value. In chronic cases there are fewer "pus corpuscles." The majority of the cells have single round nuclei. Some of them are smaller than "pus corpuscles," have very little protoplasm and are evidently "lymphoid cells." Others are of about the same size as "pus corpuscles," with large round nuclei and considerable protoplasm, and are probably "plasma cells." (Both lymphoid and plasma cells are present in large numbers in the meninges in chronic cases.)

Cultures should be made on blood serum at the time of puncture by allowing one or more cubic centimetres of the spinal fluid to drop into the culture tube. Care must be taken to prevent the fluid from running down the side of the tube at its upper part in order to avoid contamination by wetting the portion of the tube which comes in contact with the cotton. The operator should handle the end of the needle as little as possible over which the fluid runs. After obtaining the fluid in the serum tube allow it to flow over the surface of the serum and to remain in contact with it for at least a minute or two. In a number of earlier cases in which organisms were present in the cells and in which symptoms of active meningitis were also present I have failed to obtain cultures by the use of a small platinum loop filled with exudation because the quantity was too small. Furthermore, it seems probable that in a number of cases failures to obtain a growth of the intracellular diplococcus have resulted from making cultures from the sediment after the fluid has stood for several hours, even when considerable quantities of the exudation were used.

As to the variations in the turbidity of the spinal fluid and their relation to the severity of the symptoms the following results are derived from the examination of the spinal fluid from thirty cases of epidemic cerebro-spinal meningitis. In many of these two punctures were made at different times and in some cases three or four. Within certain limits there is some relation between the degree of turbidity of the spinal fluid and the severity of the symptoms. The acute cases almost always show a markedly turbid fluid during the early part of the disease when the symptoms are severe. In some cases there is an immediate formation of purulent sediment in the bottom of the test-tube, but in the majority of cases the fluid is simply very turbid and after standing contains considerable fibrin and many cells. The cases in which a purulent sediment forms may prove fatal within a few days, but, on the other hand, the same kind of fluid may be obtained in cases which are only moderately severe at the time when the puncture is made.

Moderately severe cases may show well-marked turbidity at first, and later punctures, made at intervals of several days, may show a diminution in the turbidity of the fluid and yet the symptoms may be severer than they were at the time of the first puncture. In other cases the diminution in turbidity may correspond to some extent with the improvement in the patient's condition. If the fluid in acute cases is obtained late in the disease at a time when the acute symptoms have for the most part subsided it may be clear in some cases, and the microscopic examination may fail to detect evidences of meningitis. In other cases the cloudiness may be very slight and very little fibrin and only a few lymphoid cells and "pus corpuscles" may be found by microscopic examination. So that beyond certain limits there is no constant relation between the degree of turbidity and the severity of the symptoms.

In the intermittent cases the spinal fluid may be clear during the intervals that the patient is without symptoms and become turbid again during the exacerbations. This is

Digitized by Google

by no means constant, however. The fluid is very likely to show a slight degree of cloudiness in these cases in spite of the absence of symptoms. It is impossible to say how long a slight cloudiness may persist in chronic cases. I have found more or less cloudiness due to cells in a number of chronic cases in which the disease had lasted for several weeks. From my experience thus far I would attach more importance to the results obtained by lumbar puncture than to any other means of diagnosis in the doubtful chronic cases seen late in which even slight cerebral or spinal symptoms still persisted. In mild cases the exudation may disappear from the spinal fluid in a few days. In the questionable cases in which the fluid appears to be perfectly clear it is necessary to make a very thorough examination of the bottom of the test-tube with a platinum wire after the fluid has stood for several hours.

There is no constant relation between the severity of the disease and the number of organisms present in the spinal fluid. If cultures are carefully made at the time of puncture and if the blood-serum is good one may expect to obtain a growth of the diplococcus intracellularis in the majority of acute cases provided the patient has symptoms of active disease. In a number of cases I have obtained a growth of the diplococcus after the disease had lasted for more than two weeks. In one case which lasted for five weeks I obtained growths in every one of five punctures made at intervals of one week. On the other hand, there have been cases in which the spinal fluid was very turbid and in which a purulent sediment formed and no colonies were visible on the serum after twenty-four hours, although a moderate number of diplococci were present in the water of condensation and a very few were obtained by scraping the surface of the serum with the wire. In one such case lumbar puncture was performed three days after the onset of the disease at a time when the cerebral and spinal symptoms were intense. In this case in addition to the very slight growth on the serum no organisms were found in the "pus corpuscles," although the exudation was purulent. It is difficult to give a satisfactory explanation of such cases. It seems improbable that the organisms were dead and therefore did not stain in the cells or grow on the serum three days after the onset with persistence of severe acute symptoms. One rarely obtains a growth of the intracellular diplococcus in chronic cases. In some instances, however, a few diplococci are found in some of the "pus corpuscles," and at times a limited number of organisms can be obtained by scraping the surface of the serum when there are no visible colonies. In mild cases the organisms are apparently not very numerous and one would expect to obtain a negative result so far as the cultures are concerned unless the puncture were made soon after the onset.

SUMMARY.

1. There is no constant and definite relation between the severity of the symptoms and the degree of turbidity of the spinal fluid.
2. There is little or no connexion between the number of organisms and the number of cells present in the spinal fluid.
3. In many cases there appears to be but slight connexion between the number of organisms found in the spinal fluid and the severity of the disease.
4. Unless the subsequent examination of the spinal fluid is carefully performed no deductions as to the presence or absence of meningitis are justifiable.

PROGNOSIS.

It is impossible to say how long the disease will last or what the termination will be in a given case until the lapse of a considerable interval of time during which the patient is free from symptoms. The length of this interval cannot be definitely stated, but in most cases two weeks is a safe estimate. In acute cases it is impossible to say that the disease will not become chronic or intermittent in type later. Furthermore, the disease may be moderately severe at first and increase in severity later and prove fatal. In the intermittent type of the disease the symptoms during exacerbations may be more or less severe than those of the onset. In chronic cases the mortality is estimated to be fully as high as in the acute variety. The patient may die from the results of the lesions produced early in the disease or from complications, such as pneumonia or persistent vomiting. The mortality varies very much in different epidemics. Hirsch estimates it at from 20 to 70 per cent.

TREATMENT.

Prophylactic.—Nothing of practical value is known about the method of infection or about predisposing causes. The disease is a primary infection and frequently attacks apparently healthy people; therefore no definite prophylactic treatment can be formulated. Although the disease appears to be but slightly, if at all, contagious it can do no harm, in the absence of positive knowledge as to the method of infection, to isolate the patients.

Curative.—There is no known remedy which either checks the disease or shortens its course. In a disease like cerebro-spinal meningitis, in which such marked variations in the severity of the symptoms occur at short intervals and in which so many types are observed, one must be very cautious and not confound apparent therapeutic results with coincidences. No effectual method of treatment has been suggested that I am aware of. The older methods—consisting of cautery of the spine, cupping, leeching, purging, ice-bags, and mercurial treatment—all appear to have been faithfully tried. There is no evidence that any of these procedures accomplished anything more than to increase the patient's discomfort in some instances.

Symptomatic.—Some relief from the nervous symptoms has been obtained by the use of sedatives and analgesics. It is difficult to estimate their value in such a variable disease. Delirious and restless patients are sometimes quieted by the bromides. The pain and tenderness in the head and neck may require some preparation of opium at times. Antipyrin and allied drugs have been used, but have not proved of much value unless large doses were given. The danger to be apprehended from the depressant action of these drugs is well known and it is safer not to use them. Salicylate of soda has been tried by various men in cases in which joint complications occurred. There is some difference of opinion as to its efficacy. In the cases which run a long course the most important indications are to sustain the strength of the patient by feeding and stimulation. It is important to keep a daily estimate of the quantity of food taken by these patients. In the long-continued cases the patients often refuse food for several days at a time and it is necessary to use a stomach tube in these cases at such times. This is especially the case in children. Complications must be treated as they arise. The convalescent stage is often long and requires careful supervision. The emaciation, weakness, and anæmia demand appropriate hygienic, dietetic, and tonic treatment.

In conclusion, a few words about the therapeutic value of lumbar puncture may not be amiss. The value of this procedure is purely diagnostic. One reads from time to time of recoveries from meningitis following the operation and of other cases in which the symptoms were ameliorated. I have never seen any such cases although constantly on the watch for them. A temporary relief, lasting for a few hours, has followed the operation in a few cases, but the same remissions frequently occur without any treatment. The fact that in almost all cases no change of any kind is visible in the patient's condition after the operation is strong evidence against its therapeutic value.

An extensive bibliography may be found in Councilman, Mallory and Wright's work entitled, "Epidemic Cerebro-spinal Meningitis," &c. Report of the Massachusetts State Board of Health, 1898.

WATER-SUPPLY OF PLYMOUTH.—The Mayor of Plymouth formally dedicated the new water-storage reservoir on Sept. 21st in the presence of thousands of the citizens. The reservoir, which has just been completed, is at Burrator, on Dartmoor, and was commenced in August, 1893. It has an area of 116 acres and a capacity of 651,000,000 gallons. The cost of the undertaking has been £200,000. The proceedings were of a very enthusiastic character and concluded with a banquet at the Plymouth Guildhall in the evening.

DEVON COUNTY ASYLUM.—At the meeting of the Devon County Council held recently the committee of the lunatic asylum reported that there were 1116 patients in the asylum and that Dr. George Symes Saunders had resigned after 28 years' "most able and faithful service." He has been granted a retiring allowance of £742 per annum and this amount the committee asked the Council to confirm. The report was adopted.

THE INFLUENCE OF POSITION IN FRACTURES AND DISLOCATIONS AS SHOWN BY A COMPARISON OF THESE INJURIES IN MAN AND ANIMALS.[1]

BY EDRED M. CORNER, B.SC. LOND., M.A., M.B., B.C. CANTAB.

THE various adaptations which have occurred through man adopting the erect attitude are extensively dealt with in the large text-books of anatomy. The effects of position on the soft parts have to some extent been worked out, but so far as I know no work has been done upon the effects of the quadrupedal and bipedal positions upon injuries to the bony parts. These I have tried to work out in their principal directions. The subject matter therefore consists largely of what may be called surgical mechanics, and to this I have added the data drawn from veterinary surgery.

The mechanics of the injuries to the bones and joints in man can be easily studied as there is abundant material, but it is difficult to obtain the accurate data of fractures and dislocations in animals because an attempt is rarely made to rectify these, the animals being destroyed as they have no longer their full working value. This part of veterinary surgery has never been worked up to anything like the extent that it has been in man. The differential diagnosis and treatment are very shortly treated and the etiology of fractures and dislocations is almost untouched. In order to remedy this defect to some extent I have consulted all the cases which I could find reported in British and some American literature. Upon such material it is naturally impossible to build up reliable statistics as to the relative frequency of these injuries. Still, as fractures and dislocations are rare in animals and their study apparently of little practical use, the cases are recorded even when they do not necessarily present only usual features. Again, in consequence of the procedure after injuries in animals being usually to kill and not to cure the reports generally contain, besides an account of the injuries as made out in the living, descriptions of the post-mortem conditions found. These cases which are complete are of the greatest value, and I have neglected as too indefinite most of those in which such an examination was not made. In this way I have examined the records of more than 350 cases. I propose dealing only with those injuries which occur both in man and animals under conditions that are comparable. For example, I have omitted the fractures and dislocations which are peculiar to man owing to his fore-limb being specialised into an arm. Similarly some very interesting fractures in animals have been omitted, as that of the navicular bone in the horse, on account of the fact that there is no corresponding bone in man. Because the horse is the quadruped that is most frequently damaged and has been in consequence most fully studied I have selected it as the type to compare with man.

Broadly speaking, fractures are of rare occurrence in the horse in comparison with man and dislocations are still rarer. Animals agree with man in so far that they suffer less often from dislocations than fractures. The principal mechanical reasons for the fact that dislocations are less frequent in animals than in man are twofold—namely, the very strong muscles and tendons which surround the joints and the simple, limited movements allowed in them. In quadrupeds the presence of four supports to the trunk gives great stability to the animal, but these supports, which are disposed in pairs, are differently arranged with respect to their several segments. The ways in which the different segments of the limbs are placed give rise to the principal differences in the fractures and dislocations which occur in man and animals. It will add to the clearness of the following account if I first briefly state what these arrangements are. The long axes of the ilium and scapula both make angles with the long axis of the body of about 45°, that of the former directed downwards and backwards and the latter downwards and forwards (Fig. 1). From this point the angles in both limbs differ. The ilio-femoral angle is just about 90° and the humero-scapular 105°; the femoro-tibial (knee) 90°, the humero-radial (elbow) 150°; the tibio-tarsal 135° and the radio-carpal is practically 180°, the radius, tarsus, and metatarsal bone being almost in one straight line and the metatarso-phalangeal angle is about 165° and the corresponding carpal angle 135°. Speaking generally the bones of the fore-limb approximate in some degree towards a straight line, which accords with their predominant function of weight-bearing. The hind-limb, which is eminently propulsive, has its several segments set at more

FIG. 1.

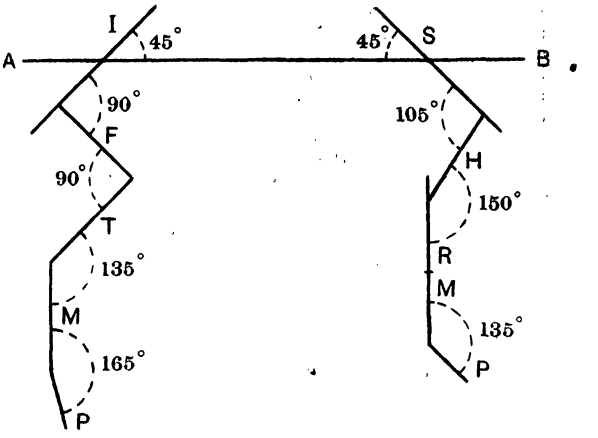

Diagram showing the relations of the segments of the fore- and hind-leg of a horse to each other. A, B, Longitudinal axis of body. Fore-limb: S, Scapula; H, Humerus; R, Radius; M, Metacarpal; P, Phalanges. Hind-limb: I, Ilium; F, Femur; T, Tibia; M, Metatarsal; P, Phalanges.

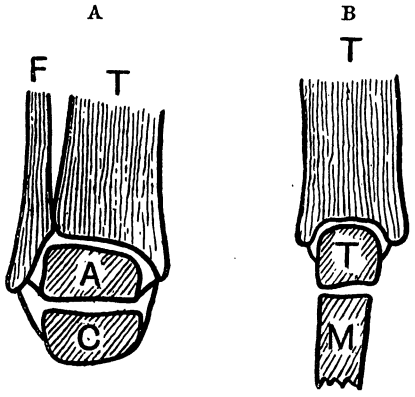
acute angles and is therefore bent in a zigzag manner like a spring. As the body-weight acts vertically at all these joints a constant strain will be thrown upon the muscles and tendons passing over them. If the ligaments bore this strain, movement in the same direction as the natural condition would be prevented. For example, the knee is naturally flexed to about 90°, and if the tendency of the body-weight to flex it further was prevented by ligaments the animal would be unable to bend its knee beyond this angle. These points will be severally dealt with in respect to their influence in the accounts of the various injuries.

FRACTURES AND DISLOCATIONS IN DIGITIGRADE AND PLANTIGRADE ANIMALS.



The first problem to be considered is the influence of digitigrade and plantigrade progression upon injuries. To make this clear the mechanical conditions must first be considered. The distance from the ground to the ankle-joint represents the length of the lever which acts on this joint. This lever, or foot-lever as it may be called, in man consists only of the astragalus and calcaneum, the total length of the perpendicular being not more than 3 in. In the horse, however, the foot-lever consists of three phalanges, the metatarsal bone of the tarsus, its length being about 18 in., the corresponding carpal lever being about 18 in. The mechanical value of this lever is, then, six or seven times greater than that in man. Besides the length of the lever its intrinsic strength must also be considered. In man it is short and thick, consisting of only two segments, which are firmly united by an inter-osseous ligament, whereas in the horse it is very long, many-jointed, and comparatively thin. In the latter, therefore, although the foot-lever has from six to seven times the mechanical value that it has in man, it is relatively weaker. The socket in which this lever works will materially influence dislocation in two ways, by its size and depth. Both these conditions must be gauged relatively to the length of the foot-lever, the absolute size and depth being of no value in comparisons. The ankle-joint is relatively larger in man and it is also deeper inasmuch as the malleoli are relatively longer. As in the horse the mechanical advantage of the foot-lever is much greater and it plays upon a relatively small and shallow socket it might be expected that dislocation would occur more commonly than in man. This, however, is not so; Müller says he knows of no cases of such a luxation. The

[1] Thesis for the degree of M.B. in the University of Cambridge.

Digitized by Google

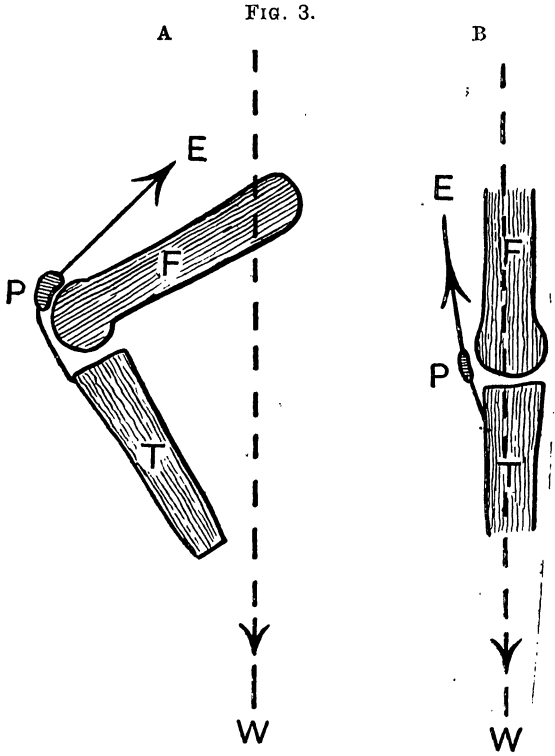
explanation therefore must undeniably lie in the weakness of the foot-lever. This, as has been said, consists of many parts which are bound together by very strong ligaments. Instead of these dislocations of the ankle it is found that the foot-lever breaks and the records show that the bones break before the ligaments. The metatarsal and metacarpal bones form just over half the length of each foot-lever and, as might be expected, are the bones most frequently broken. The metacarpal bone is broken more frequently than the metatarsal, probably in consequence of its being more exposed to injuries, such as in stumbles, turning, &c. I examined the records of 15 cases of the former and 5 of the latter. The bone next commonly broken is the long (first) phalanx, 10 cases; then the middle phalanx, 6; and finally the os pedis, 5. It is of interest to note that the order of frequency of fracture decreases with the length of the individual bones. Accordingly these considerations show that fractures of these bones are of greater frequency among those in the horse than they are in the case of man. In man, with his relatively short, broad foot-lever and large ankle-socket produced by the long malleoli, it is to be expected that these latter processes are more likely to be broken off than in the horse (Fig. 2 A). Such is certainly the case, for

FIG. 2.

A, Diagram of bones about the ankle-joint of man. T, Tibia. F, Fibula. A, Astragalus. C, Calcaneum.
B, Diagram of bones about the ankle-joint of the horse. T, Tibia T (on the small bone), Tarsus. M, Metatarsus.

dislocation in man at the ankle is extremely rare without such a fracture. In the horse Leisering records such a fracture found post mortem and Müller suggests that Louchard's case may have been another. These are the only two cases I could find. Besides the dislocation of the ankle-joint with fracture of the malleoli, plantigrade animals differ from digitigrade animals in having the calcaneum fixed by contact with the ground. By virtue of this they are liable to astragaloid and subastragaloid dislocation. Digitigrade animals are exempt from these injuries as the calcaneum is never so fixed. Owing to the plantar arch in man the calcaneum is directed backwards and downwards and is fixed by contact with the ground only at its hindermost part. In consequence, the whole length of the calcaneum acts as a lever to break the inter-osseous ligament between it and the astragalus. There is a similar lever from the heads of the metatarsal bones to the tarsus.

Another point in connexion with dislocation at the ankle-joint is that in man the movements permitted there are more extensive. This certainly gives an additional liability to dislocation but may also save him from injury. For instance, violence applied to the outer side of the foot in man may result in nothing more than a sprain of the ligaments, but in the horse in which the movements at the ankle-joint are limited such violence is very liable to lead to fracture. The ankle-joint in the horse forms anteriorly an angle of 135°, whilst the wrist is practically in one straight line with the arm. There will be a constant strain upon the calcaneum, which is very rarely broken in the horse; it is then usually broken by muscular violence. Such an accident occurs very rarely in man, as for instance when he adopts digitigrade progression, as in running, jumping, &c.



FRACTURES OF THE FOREARM AND LEG.

The tibia is the most commonly broken bone in animals. In its causation it differs from that in man by being almost invariably caused by direct violence, whilst in man such a cause is uncommon. As a result of this transverse fractures are commoner in the horse than in man and in transverse fractures the ends of the bones are not unlikely to remain in apposition. It is not therefore surprising to find cases recorded in veterinary literature in which displacement did not occur for some days after the receipt of the injury. This period is of very variable length, as from five to thirty days or more. Williams asserts that in such cases the damage is probably subperiosteal and that this membrane being very strong is sufficient to retain the two fragments together. Nowhere have I found the possibility of impaction considered, though it is not so likely to occur with direct violence. Cases in which displacement does not occur early, as when the bone is broken transversely, do occasionally occur in man. This cannot occur often, for the most common fracture of this bone is produced by indirect violence and the line of fracture is in consequence more or less oblique. Fractures of the fibula are very common in man, whilst in animals with well-developed fibula it as a rule only occurs as the result of direct violence. In the horse the fibula is defective and only exists in the upper third of the leg; Müller asserts that it is never broken. The tibia of the horse has an outer malleolus as well as an inner supplying the wants of the lower end of the fibula (Fig. 2 B). I have shown above that neither malleolus is at all likely to be broken. The radius in the horse is similarly placed to the tibia and suffers, as would be expected, similar fractures. The ulna is only a fine splint-like bone in the horse in its lower part and is very rarely broken. Like the fibula it is sometimes broken by direct violence in cats, &c. The olecranon will be considered after the patella.

FRACTURE OF THE PATELLA.

Gurlt's statistics give the frequency of the fracture of the patella in man as 1·4 per cent. of all fractures. The veterinary text-books state that this fracture is very rare and that when it occurs it results from direct violence; the more

FIG. 3.

A, Diagram of knee of horse. B, Diagram of knee of man. F, Femur. T, Tibia. P, Patella. E, Line of action of quadriceps. W, Line of action of body-weight.

recent works add muscular violence. In a search through American and British literature I have been unable to find a single case. In the horse the knee is naturally flexed to an angle of about 90°, and as the line of action of the body-weight is vertical there will be a continuous strain on the

Digitized by Google

patella. This strain cannot be resisted by the ligaments, as then further flexion would be prevented, and this is certainly not the case. The strain must therefore be borne by the quadriceps extensor, the patella, and its ligament. With the assumption of the upright position such continuous strain will be lost, as the body-weight is transmitted directly from the femur to the tibia. Both Humphry and Goodsir, later also Meyer, obviate muscular action in their theories of the mechanism of the knee in standing. The patella has therefore lost in man a great deal of its function and may therefore be said to be atrophic. A limit is placed to this atrophy by the value of the patella in walking, running, &c.—i.e., when the knee is flexed. Besides this, in the flexed knee of the horse the patella has to transmit the force through an angle (Fig. 3), and consequently must be a much stronger bone than if it had merely to withstand a nearly pure traction force, as in the straight knee. In adopting the erect attitude the ligamentum patellæ has been shortened, so to speak, in order to take in the slack. Man's patella, therefore, rides relatively lower on the femoral condyles than in the horse. This enables it to be in contact with the femoral condyles near its middle and not at the ends. The area between the two horizontal lines on the articular surface indicates this area of contact. The bone is consequently snapped by the contraction of the quadriceps muscle. This is the usual method given to explain the fracture by muscular violence, but a most important factor is not considered. The knee is flexed at the time and in consequence the body-weight will work hand in hand with contractions of the quadriceps.

In the horse, then, we have a stronger patella which by means of a longer ligamentum patellæ rides higher on the femoral condyles. Nearly the whole of it is in contact with the femur at the same time. Therefore it differs from man's in being almost entirely out of harm's way. Considering these points and the extreme rarity of the fracture it is very improbable that it is ever broken by muscular violence. The statement to this effect in the veterinary works in all probability arose from the observations in the treatises on the surgery of man. Mr. Anderson shows that this injury is more common in people of feeble habit of body from the St. Thomas's Hospital returns of 1880–1890. This frequency, he says, "points to the predominant influence of a second factor, a diminished textural resistance in the bone." To this may be added other clinical facts. It is by no means infrequent to find refracture in a different place after wiring has been done. May it not be that here a new piece of cloth has been put in an old garment? Again, one often sees cases of fractured patella in whom the other patella has been broken before or which breaks subsequently. Mr. Anderson has on clinical grounds pointed out an atrophic condition of the patella related to the age and condition of the subject. This is a condition of the individual and differs from the suggestion I have made from our ancestry. To these must be added Poirier's evidence of the great diminution of the compact bone with increase of age.

Comparing the patella of man with that of a typical quadruped it is seen that the former is relatively shorter and broader, its breadth equalling and usually exceeding its length. It is thinner also, as is shown by calculating its thickness even in terms of the relatively shorter length. Thus it may be said to be the weaker, and this is supported by comparing sections of the bones. In man there is less compact tissue round it and the cancellous tissue has wider meshes and weaker trabeculæ. The structure of the patella on all points bears out the weaker condition found in that of man which had been suggested above from *a priori* reasoning.

FRACTURE OF THE SESAMOID BONES.

One of the most interesting fractures in the horse has no counterpart in man, but as the bones are placed under somewhat similar circumstances as in the patella I will give a brief account of them. The sesamoid bones are strong masses in the flexor tendons situated on the metatarso-phalangeal and corresponding carpal joint (Fig. 4). The joint is hyper-extended to an angle of about 135° and in consequence of the vertical line of action of the body weight a constant strain is borne by these bones. As they are situated over the joint they are more similarly situated to the human patella, but they agree with the quadruped's in that they are in contact with the overlying bones in almost their entire length. They are therefore not liable to be broken across the lower end of the metatarsal bone. Fracture occurs by muscular violence and differs from the common results so produced in the extraordinary comminution which takes place. The bones are broken in as many as from 5 to 30 pieces; the fracture may also occur in all the fore-limbs simultaneously. I have analysed eight papers upon this subject. Hart of Calcutta says that it was the commonest] fracture which he had to deal with, and that it occurred chiefly in young horses from Australia after a voyage of from 60 to 70

FIG. 4.

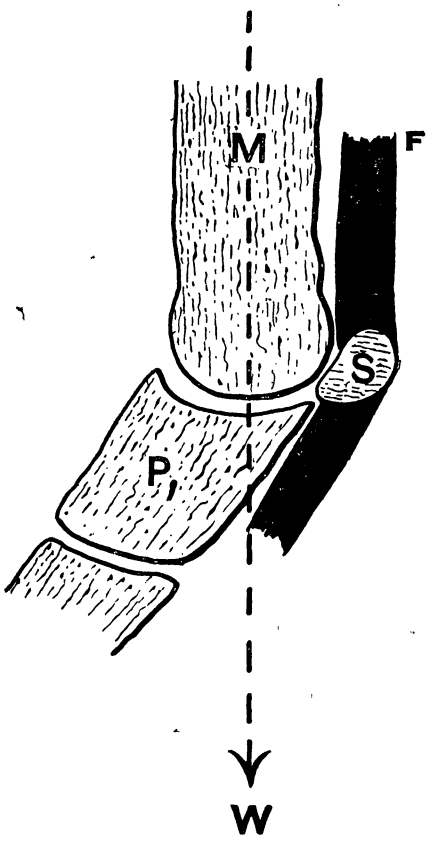


Diagram of metacarpo-phalangeal joint of horse. M, Metacarpal bone. P1, Proximal phalanx. S, Sesamoid bone in flexor tendon F. W, Line of action of body-weight.

days, during which they stood continuously and suffered the greatest privations. When landed they bolt maniacally and after going a short way collapse. Post mortem he demonstrated that the sesamoid bones were lighter and more cancellous than normal. Professor Varnell previously had also described the same morbid condition as predisposing to the fracture, but offered no suggestion as to the cause of it. Hart also showed that if care was taken in landing and for some time afterwards this predisposing condition could be recovered from. Both the above authorities have shown the predisposition, but have not worked out the mechanism of the fracture. The bones are situated over the metatarso- and metacarpo-phalangeal joints and also lie in contact with the bones; the joint is hyper-extended to 135° from the vertical. As the animal gallops, each time its legs touch the ground, a violent strain will be thrown on the flexor tendons and the sesamoids. Also, as the bones lie directly over the joint, the lower end of the metatarsal bone will be driven violently upon them. This action will be somewhat like that of a hammer, and considering the great tension on the bones the resulting comminution may be explained. In Hart's cases besides the predisposing condition of the bones there is the excessively violent muscular action from the excitement of landing after the long voyage.

A point which may deserve explanation is that in from 60 to 70 days of standing could atrophy be induced in the bones? Such conditions should normally produce an hypertrophy, but continuous strain with the malnutrition and greatly impoverished health might produce the atrophy. Leisinger records a case of transverse fracture, the bones being probably broken across the lower

Digitized by Google

end of the metatarsal bones. The sesamoid bones, therefore, present an intermediate condition to the patellæ of man and quadrupeds. They agree with those of man in being broken by indirect violence, but by virtue of being completely in contact with the underlying bones and bearing a continuous strain, differ from it in being broken into several pieces and not into two by a transverse break; they are also placed over the joint, and, though very rarely, are broken transversely by muscular violence. They agree with the horse's patella in being subjected to the continuous strain and being in almost complete contact with the underlying bone, but the horse's patella differs, as shown above, in being situated so as to be practically out of harm's way with respect to indirect violence. They also illustrate the influence of the individual's condition as predisposing to fracture. The joints over which they are placed are set at different angles, the foot 165° and the hand 135° (Fig. 1), and it might therefore be expected that the fore leg sesamoids would be more frequently broken than those of the hind leg. This will certainly to some degree be balanced by the fact that in the legs greater muscular action will be experienced.

FRACTURE OF THE OLECRANON.

The olecranon in the arm corresponds in some degree to the patella in the leg. Owing to the specialisation of man's arm the conditions cannot be compared with advantage; in the horse the condition of the fore-limb is to some extent the same as the hind-limb and a comparison may here be made. Though the olecranon is suitably placed for being broken across the trochlea of the humerus it is hardly ever so fractured. Pernaud records such a case in the horse. Cases are occasionally recorded in which fracture has occurred on a level with the upper end of the radius, but they are scarcely cases of fracture by muscular violence. The reason why it is not more frequently broken probably lies in the fact that the fore leg is mainly of use for weight-bearing and the hind leg mainly for propulsion. In this way the olecranon to a great extent is saved from the violent intermittent contractions of the extensor muscles; should the patella have been continuous with the tibia it must inevitably have been broken off. That the fore leg is of less value in violent movements is indicated by the fact that the shoulder-girdle is nowhere in bony connexion with the trunk, the clavicle of course being absent. As the humero-radial angle is only 150° and not 90° (Fig. 1), as in the knee, the olecranon is not so well situated for fracture as a like structure would be at the knee.

FRACTURES OF THE HUMERUS AND FEMUR.

Fractures of the humerus and femur may be dismissed in a few words. They usually result from direct violence. In the case of the femur of animals the neck is not usually so marked as in man, and, as Müller has pointed out, it is probably less commonly broken. When compared with man both these bones form an angle of 45° to the long axis of the body. In consequence a continuous strain is thrown on the glutei, supraspinatus, infraspinatus, &c., which has led to the enormous development of the tuberosities of the humerus and of the trochanters. The presence of the third trochanter in animals is probably accounted for in this way. Steel records a case in which this was torn off by muscular violence. Besides the third trochanter being present and the large size of the other trochanters the constant strain may account for the shorter neck to the femur, for the longer the neck the greater the mechanical disadvantage of the glutei.

FRACTURES OF THE TRUNK.

The scapula is uncommonly broken in the horse on account of its sheltered position and of its mobility due to absence of the clavicle. Excluding chipping of the glenoid cavity I analysed only 6 cases, none of which presented any features of interest. The pelvis in the horse is far more frequently broken than the shoulder girdle, as might be expected. I collected 25 cases of this fracture, 11 of which were multiple, 6 of the ilium only, 4 of the acetabulum only, and 4 of the ischium only. A favourite situation for fracture is at the narrow neck of the ilium. The ratio of the breadth of the neck to that of the expanded part of the ilium is in the horse 1 in 6, in man 1 in 3. The neck of the horse is relatively less broad and is not thicker. Force applied to the crest of the ilium has the length of the bone for a lever and this lever is longer in man and also possesses a relatively weaker point in the neck, and it is here that the fracture occurs most commonly in the horse. This constitutes a most important distinction to the fractures in man. A similar remark would apply, though with considerably less weight, to the fractures of the ischium in the horse. The position of the pelvis in man and in animals seems to exercise little influence upon its liability to fracture.

The ribs in the horse are occasionally broken by muscular violence, but far more commonly by direct violence. Gabriel records a case of fracture of the first rib by muscular violence during turning. In man the clavicle protects the upper ribs; in the horse this bone is absent, but the position of the fore legs protects them. Müller quotes the returns of the Prussian army for 1891 and gives the fractures of the vertebral column as 30 cervical, 6 dorsal, and 3 lumbar. Of the 22 cases I examined 11 were cervical, 4 were dorsal, and 7 were lumbar. Pure dislocation as in man is very rare and occurs only in the cervical region; a partial dislocation or subluxation occurs more frequently in the horse. The cervical vertebræ most commonly involved were the second, third, and fourth. Fracture alone was commonest in the lumbar region and here the first lumbar vertebra was the usual one broken. The twelfth dorsal was the one most frequently broken of this set. So far they agree with the conditions of man's injuries. But owing to the vertebral bodies articulating with each other by means of a kind of ball-and-socket joint the vertebra in front may be split by that behind. Such a case is recorded by Smith, where the fourth cervical vertebra split the body of the third. The coccygeal or caudal vertebræ are for obvious reasons broken more often in animals than in man. The sacrum is quite as true to its name in animals as in man, being rarely if ever broken.

Of 21 cases of fractured jaws in animals 3 were of the upper and 18 of the lower. Of the latter 5 occurred in the symphysis, which is probably a higher percentage than in man and probably due to the weak union found at the symphysis in animals. The squarer jaw in man allows more easily of fractures to occur other than at the symphysis. Of fractured skull there is little to be said, except that I found recorded 10 cases of the vault (2 frontal, 4 parietal, 2 occipital, and 2 general) and 3 of the base.

DISLOCATION OF THE PATELLA.

Though fracture of the patella is one of the rarest fractures in the horse yet dislocation is the commonest luxation. Around this luxation has cropped up a considerable literature. Certain papers illustrate the interesting evolution of the knowledge of this condition and its mechanical causation. I give a short epitome of them. Spooner says that these cases were taken for cramp; Duboisin describes cases of femoro-popliteal neuralgia. In these last papers Professor Youatt adds an editorial note that the cases are those of dislocation outwards of the patella. "An old practitioner" next frankly narrates the trouble he had with a case and Professor Youatt again enlightens us. The luxation was attributed to mechanical causes such as uneven ground relaxing the extensors; similarly fracture of the neck of the ilium was found to cause it. It was then said that ill-health relaxed the ligaments and led to the absorption of the fat behind the patella and its ligaments and so allowed the luxation. This condition disappeared on return to health. With Golding begins a period of inquiry; he asserted that ill-health and non-development of the femoral condyles caused it. Professor Axe wrote a paper on Adynamic Luxation, giving conditions like those mentioned above. Professor McCall then put forward the various mechanical conditions which might lead to luxation. He added several new ones, as vertical position of the femur, hydrops articuli, &c., to the list. Dollar, in a paper written a little later quotes Chuchu, who says that the luxation is only partial and that the patella gets engaged with the knob of the internal femoral condyle. He also quotes M. Violet, who regards spasm of the internal vastus or paralysis of its antagonistic muscles as a factor. Dollar himself advocates Chuchu's views. Tweedley gives a careful account of dissections he did on these subjects. He supports Chuchu in asserting that the luxation is partial and due to the patella's "temporary arrest on the superior entablature of the femoral condyle." This hooking with the internal condyle he says is aided by the various conditions mentioned above and he gives the muscular spasm after galloping as the occasional cause. Müller now divides the luxation into two classes, dislocation upwards and dislocation to the side, nearly always to the outer side. I have come across only one

Digitized by Google

notice of the inward luxation of the patella in a horse and that is recorded by Pernaud.

As has been said, in the horse the patella lies relatively higher on the condyles as the ligamentum patellæ is longer and so is thus allowed greater amplitude of lateral movement. In the partial dislocation the flexed knee with the constant strain on the extensors, &c., aids considerably in the locking of the bones. The very large internal condyle prevents the inward dislocations. The continuous strain will also tend to prevent the displacement of the patella round its long axis. I have found no reference to such a displacement in veterinary literature. In man, as in the horse, dislocation outwards is by far the commonest. It also agrees in being most frequently only partial, but owing to the erect position the partially dislocated bone is not fixed by the weight of the body as in the horse. The lower end of the femur in man differs from that in the horse in the external condyle and its articular surface extending higher up the front of the femur than the internal, where it is also more prominent. In the horse precisely the opposite condition exists, yet in both cases outward dislocation is the commonest. The explanation probably is that in assuming the erect attitude the extensor muscles have acquired a more outward pull; the pelvis is broader and the knees are closer together under the body. The same explanation is also a factor in the condition of the external condyle in man mentioned above. The inward pull of the extensors, the knees being widely separated, in the horse will also aid the upward extension and prominence of the internal condyle. The existence of complete inward dislocations of the patella in man has been questioned by Malgaigne and denied by Nélaton and Streubel; Hamilton quotes one case of partial luxation reported by Key. Pernaud's case is the only one which I have found in animals, and this was probably only partial. Many of the mechanical points mentioned in the history of dislocation of the patella in the horse apply equally to man's. The non-development of the femoral condyles may explain some of the cases of congenital luxation in man.

DISLOCATIONS OF THE SHOULDER.

Dislocations of the shoulder are rare on account of the absence of the clavicle allowing more mobility of the scapula besides other general reasons. It shows especially well how simple movements affect the liability to dislocation. In man force transmitted up the humerus, as in falling, is not directed to the glenoid cavity but to the side of it, and so the bone is easily dislocated; in the horse the simple movements practically only allow of the direct transmission to the glenoid cavity. The accident mainly occurs in the hunting field, as when landing from a jump with the fore legs thrust forward. The line of the humerus is then about vertical, as it is normally directed backwards, making an angle of 45° with the long axis of the body. In this position the head of the bone may escape in almost any direction. As the tuberosities are very large from the continuous strain on the supraspinatus, &c., the head of the humerus is more likely to escape inwards—i.e., subcoracoid. Still it is to be expected that subspinous dislocations should be relatively more common than in man. The veterinary text-books unanimously state that subcoracoid dislocation is the commonest and do not mention subspinous at all. Dr. Phineas Abraham questioned this and recorded a case of his own and two under the care of Professor Robertson in which post mortem the humeral head was found on the dorsum scapulæ. In the veterinary literature I found records of 4 other cases, but not one of these can be surely put into any class. In man, as is well known, subcoracoid dislocation is frequent whilst subspinous is rare. Dislocation of the shoulder in the horse is almost invariably associated with chipping of the glenoid cavity, probably due to the very large tuberosities of the humerus or the difficulty that the head of the bone has in escaping owing to the simple and not extensive movements allowed. In man for the very reverse reasons the edge of the glenoid cavity is uncommonly chipped. In him also fracture of the humerus with dislocation is more common, and this is especially true of separation of the epiphysis

DISLOCATION OF THE HIP.

I collected three instances dealing with dislocations of the hip in animals. Two were certainly on to the dorsum ilii and one into the obturator foramen; in the others no post-mortem examinations were made as reduction was accomplished. Cattle have a shallower acetabulum and are more liable to this dislocation. From *a priori* reasons it might be expected that dislocations into the sciatic notch should occur more frequently than in man, and with the head of the femur escaping inferiorly thyroid also. In the skeleton the cotyloid notch in the acetabulum of the horse is extremely large and, though spanned by the transverse ligament, might well aid to a greater frequency of thyroid dislocations in them. In conclusion, it may be noted that in looking through the fractures in animals there appears to be a marked absence of cases in which impaction occurs and again of separation of the epiphyses as compared with man.

SIX CASES OF MALIGNANT DISEASE OF THE CERVIX UTERI TREATED BY VAGINAL HYSTERECTOMY.

BY FREDERICK J. McCANN, M.D., C.M. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS AT THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, LONDON.

CASE 1.—A married woman, aged fifty-four years, was admitted into the Samaritan Free Hospital on July 13th, 1896. Her previous history was as follows. At the end of February she had noticed a discharge of blood from the vagina. This continued daily until her admission into the hospital. The discharge was never offensive. She did not complain of any pain and was always able to work. For two months previously to her attendance at the hospital the quantity of the discharge had increased. She stated that she was losing flesh. The menopause had occurred seven years previously. She never had any vaginal discharge until the present trouble commenced. She had had five children (twins twice) and two miscarriages. The last child was stillborn. On examination she was found to be fairly well nourished, with no cachexia. Her appetite, she said, was good and she slept well. On bimanual examination the uterus was found to be freely moveable. There was no infiltration of the broad ligaments. A nodular growth was felt, involving chiefly the posterior lip of the cervix and extending upwards into the cervical canal. The appearance of the growth *per speculum* suggested malignant disease, the surface bleeding readily when touched. On July 17th I performed vaginal hysterectomy. The method adopted was that of ligaturing the broad ligaments with silk from below upwards and separating the uterus with scissors after the application of each ligature. The operation occupied 35 minutes. The convalescence was uninterruptedly good, the patient getting up on the fifteenth day and leaving the hospital three weeks after the operation. Sections made from the growth showed that it was a columnar-celled epithelioma. I saw this patient on May 11th, 1898. There was no trace of recurrence.

CASE 2.—A married woman, aged thirty-one years, was admitted into the Samaritan Free Hospital on Dec. 14th, 1896. For a period of five months she had suffered from loss of blood from the vagina after sexual intercourse. During this period also a profuse, foul-smelling discharge had been flowing from the vagina. Her menstrual periods were regular, lasting from three to four days, until five months previously. She had had two children and no miscarriages. The youngest child was six and a half years old. (It may be mentioned

Digitized by Google

that her husband had a chronic gleet.) On examination she was found to be a stout woman of small stature and of somewhat anæmic appearance. She complained of sacrache and loss of appetite and said that she was gradually losing flesh. On bimanual examination the uterus was found to be directed backwards and freely moveable and the broad ligaments were free from disease. A rounded, punched-out surface was felt on the posterior lip of the cervix which extended into the cervical canal. The edges of the ulcerated area were hard and were composed of a series of nodules and similar nodules formed the floor of the ulcer. These nodules could be seen *per speculum* and also the surface of the ulcer, which was bathed with purulent secretion. On Dec. 17th I performed vaginal hysterectomy, adopting the method already described. A portion of omentum was found adhering to the fundus uteri. This was ligatured and dropped back. In addition the vaginal walls were united with silkworm gut sutures, an orifice being left in the centre through which a strip of iodoform gauze was inserted for drainage. The operation occupied 50 minutes. The convalescence was uninterruptedly good, the patient getting up on Jan. 3rd, 1897, and leaving the hospital five days later. Sections made from the diseased area showed it to be a squamous-celled epithelioma. I have seen this patient recently and there appears to be no trace of recurrence.

CASE 3.—A woman, aged forty-nine years, a widow, was admitted into the Samaritan Free Hospital on May 7th, 1897. Nine months previously, after receiving "an injury to her side," she noticed that she had a blood-stained discharge, which continued until Christmas, 1896, when it became offensive. In January, 1897, a quantity of the growth from the cervix was scraped away and portions were sent to the Clinical Research Association. The scrapings were reported to be sarcomatous. After this operation the discharge ceased for four weeks. I saw the patient in consultation with my friend, Mr. Laird-Cox of Southborough, and on vaginal examination we found a growth of about the size of a billiard ball extending from the margins of the cervix uteri into the vagina. Owing to the size of the growth the posterior relations could not be definitely ascertained. The body of the uterus was enlarged and freely moveable. I advised vaginal hysterectomy. The patient, a stout woman, was very anæmic from loss of blood. She had suffered for some time from a winter cough. She did not complain of any pain until a fortnight before the operation, when she had sacrache. She had not lost flesh. She had been married for thirty years and had been a widow for three years. She had had two children, the youngest child being twenty-nine years of age. The menstrual periods were of the regular twenty-eight-day type and the quantity was moderate. Her father, who is alive, had had a rodent ulcer removed from his face four years before, and his four sisters had died from cancer. I performed vaginal hysterectomy on May 11th. The growth, which in appearance resembled wash-leather, was very friable, a considerable portion of it being scraped away by the fingers. The scraping caused free hæmorrhage, which was arrested by ligaturing the base of the broad ligament on either side. The usual incision was made around the cervix and the bladder was with some difficulty separated anteriorly owing to inflammatory thickening. The posterior vaginal wall was separated, and the peritoneum being exposed was snipped with scissors and the finger was introduced into Douglas's pouch. It was found that several small fibroids were attached to the body of the uterus and that larger fibroids were growing into the broad ligaments. These fibroid outgrowths prevented the uterus being pulled down. As the fibroid growths appeared to be smaller on the left side it was decided to free the uterus on that side by ligature of the broad ligament from below upwards. The anterior peritoneal pouch was opened and the bladder and ureters were carefully separated. When the uterus was freed on the left side it could be pulled down by the vulsellum, thus allowing the right broad ligament to be ligatured from above downwards external to the fibroid outgrowths. There was no bleeding after the uterus was removed. The ovaries were left. The operation occupied one hour and forty minutes. The patient was somewhat collapsed after the operation, but she soon recovered. Sections made from the growth showed it to be a round-celled sarcoma. The patient was able to leave her bed on May 27th and she left the hospital on June 8th. I have recently heard that she continues in good health.

CASE 4.—The patient in this case was a married woman, aged thirty years. For a year and nine months she had noticed a profuse vaginal discharge which was occasionally offensive and blood-stained. This discharge was increasing in amount and was kept in check by injections. There was also pain across the sacrum. The menstrual periods were irregular in quantity, of the twenty-eight-day type, and lasted from four to five days. The quantity of the menstrual discharge, she said, had been less for the previous six months and for twelve months she had been getting thinner. The sacrache had increased, and this together with pain in the left iliac region had interfered with her sleep. She had had three children and one miscarriage. The age of the youngest child was three and a half years. The miscarriage occurred six months after the birth of the last child and was at the third month of pregnancy. There was no family history of malignant disease. On May 15th, 1897, a scraping operation was performed and it was then the opinion of two specialists that the disease was too far advanced for any radical operation. I saw the patient about three weeks later and found her to be a well-nourished woman of medium height, anæmic, and very nervous. On bimanual examination the uterus was found to be freely moveable and the cervix to be excavated by a hard nodular growth which bled easily on touching. The disease had spread to the attachment of the vaginal wall anteriorly, and posteriorly it involved the lip of the cervix. The appearance of the growth had been altered by the previous scraping operation. I recommended vaginal hysterectomy, which was performed in a nursing home on June 3rd. The usual anterior and posterior incisions were made and after partial anterior separation of the bladder and the posterior vaginal wall the bases of the broad ligaments were ligatured to arrest the bleeding from the growth. The further separation of the bladder was continued and the anterior pouch being opened the fundus uteri was drawn outwards by a vulsellum and the broad ligaments were ligatured from above downwards, care being taken to remove as much of each ligament as possible. After cutting away the uterus a diseased portion on the left side still remained. This was clamped by a pair of large Spencer Wells forceps, pulled out, ligatured, and cut off. The pelvis was raised during the operation. The pouch of Douglas was carefully sponged out, and all the ligatures were cut short. The vagina was plugged with iodoform gauze. The operation lasted one hour. The patient left the nursing home three weeks after the operation. Sections of the growth showed it to be a columnar-celled epithelioma. The improvement in the condition of the patient was most marked. She had been subject to menstrual headache, and this completely disappeared after the operation. Her weight, too, increased. On Oct. 11th it was 10 st. 8¾ lb.; on Nov. 11th it was 11 st.; on Dec. 11th it was 11 st. 2½ lb.; and on Jan. 10th it was 11 st. 3¼ lb. She was, moreover, enabled to lead an active life. On April 8th, 1898, I made a vaginal examination, finding a papillomatous mass on the left extremity of the cicatrix. I recommended that this should be removed, and accordingly on April 16th the operation was performed, the patient being anæsthetised. There was thickening around the scar which was freely moveable, but whether this was malignant or inflammatory I could not ascertain. The patient has been very well since this operation.

CASE 5.—A married woman, aged forty-six years, was admitted into the Samaritan Free Hospital on June 24th, 1897. For six months previously the patient had had a feeling of enlargement of the internal genital organs with bearing-down pains which interfered with her sleep. She also had a profuse offensive brown discharge which was occasionally watery in consistence. There was no hæmorrhage except at the menstrual periods. The menstrual periods were very irregular. Occasionally they occurred every fourteen days, at other times every twenty-eight days, and were very profuse. Previously to the attack the menses had been regular and their duration had been seven days. She also stated that she had been getting thinner. Her mother was alive and was healthy, and her father had died aged seventy-eight years, as she said from "old age." The patient had two brothers and six sisters, all of whom were healthy. She had had 13 children, the last being born on March 29th, 1892, and eighteen months later she had had a miscarriage at her second month. She was found on examination to be fairly well nourished, but she was anæmic. Bimanual examination showed that the uterus was moveable, and the fundus could be felt about 1½ in. above the pubic symphysis. The cervix was nodular and excavated. The growth encroached on the bladder anteriorly and affected the posterior lip of the cervix. On June 28th I performed vaginal hysterectomy. An

Digitized by Google

incision was made posteriorly and the posterior vaginal wall was separated. Then an anterior incision was made, but as the growth tended to invade the base of the bladder considerable difficulty was experienced in the separation of that organ. The base of the broad ligament on each side was now ligatured, the finger being introduced as a guide into Douglas's pouch. As the uterus was not easily pulled down the upward separation of the bladder was continued and after opening the peritoneal cavity the fundus uteri was pulled out by a vulsellum. By this means the left ovary was pulled into the wound and removed after ligature by the Staffordshire knot. The broad ligaments were now ligatured from above downwards. The right ovary was not removed. Considerable separation of the bladder on the right side was required. Owing to the extension of the disease posteriorly and to the right it was found that the ligature first applied to the right broad ligament was not beyond the disease. Another ligature was accordingly applied externally and the diseased portion cut off. Some vessels required ligature after the removal of the uterus. It should be mentioned that during the operation there was a sudden flow of a quantity of muco-purulent material from the uterine cavity. The vagina was swabbed out with corrosive sublimate solution and packed with iodoform gauze. The operation lasted an hour and twenty minutes. The patient rallied well after it and became rapidly convalescent. She was able to leave her bed on July 10th and was discharged from the hospital on the 21st. I saw her again on Oct. 2nd, when she said she felt much better and her appearance had certainly improved, but she had not gained flesh. She had had some abdominal distension and epigastric pain. The tongue was furred. The bowels acted regularly. On bimanual examination there was found to be hard nodular infiltration of the pelvic cellular tissue which could be felt posteriorly and laterally. There was no discharge or hæmorrhage. On Nov. 27th I saw her with her medical adviser, Mr. Huggins of Islington. Her liver was enlarged and nodular, reaching to the level of the umbilicus. The gall-bladder was distended and acutely painful on pressure. She had constant vomiting, which did not yield to the usual remedies. The vomit was green in colour and accompanied by severe pain in the epigastrium and in the left hypochondrium. On Dec. 9th Mr. Huggins kindly wrote to me intimating that the patient had died, "literally starved to death, never retaining any food." No post-mortem examination was obtained. Microscopic examination of the specimen showed it to be a malignant adenoma of the cervix uteri. The growth was composed of tubules lined with a layer of columnar nucleated epithelium. These tubules were embedded in a matrix of fibrous tissue. In this case there was local occurrence together with the formation of secondary deposits in the liver. The disease was therefore of a very malignant type.

CASE 6.—A widow, aged sixty-one years, was admitted to the Samaritan Free Hospital on Jan. 3rd, 1898. Menstruation, it was said, had occurred twice at the age of twelve years. It then ceased until she was twenty-one years of age. After this age the menses were regular and profuse, of the twenty-eight-day type, and lasting one week. Ten years previously she had had "flooding" which lasted for five weeks. She had had a return of the bleeding twice and finally there was entire cessation of this loss of blood until eight months before her admission into the hospital. For eight months she had had a slight loss of blood from the vagina at intervals of from three to four days. This continued until two months before her admission, when she had what she called a "liver attack," there being afterwards no bleeding for a month. After this the bleeding returned and was more profuse. There was also a slightly offensive discharge, but she complained very little of pain. This pain was in the sacral region and the hypogastrium, corresponding to that experienced at her monthly periods. She had been getting thinner for eight months and her appetite was impaired. She had had four children and no miscarriages. The last child was born twenty-eight years before and she had been a widow for twenty-three years. Her father died at the age of seventy-three years from chronic rheumatism and her mother at the age of seventy-four years from "old age." She has one brother and four sisters alive and healthy. She was seen on examination to be a tall, thin woman, markedly sallow in complexion. She admitted that she took too much alcohol. On bimanual examination a nodular ulcerated surface was felt involving chiefly the posterior lip of the cervix and extending to and involving the posterior vaginal wall. The uterus was moveable and was not enlarged. On Jan. 8th, 1898, I performed vaginal hysterectomy. The posterior incision was prolonged downwards along the posterior-vaginal wall in order to excise the disease which had spread in that direction. There was some difficulty in separating the bladder. The broad ligaments were secured, three ligatures being used on each side. The uterus was removed and the vagina was packed with iodoform gauze. The patient made an excellent recovery. She got up on Jan. 24th and left the hospital on Feb. 2nd. Microscopic examination showed the disease to be a columnar-celled carcinoma. This patient has remained well.

Remarks.—These cases illustrate the varieties of malignant disease met with in the neck of the womb. In four of the cases the malignant disease was discovered at a comparatively early stage, thus making the ultimate progress much more favourable. It is difficult, and in many cases impossible, to state the exact duration of the disease. Most cases have at first no symptoms at all or the symptoms are so slight as to attract little attention. The sufferers, therefore, do not seek advice till the disease is far advanced. There is no way of making sure of the beginning even if we were constantly examining, though microscopical examination of excised portions may lead to the detection of the earliest stage. Statements as to the duration of the disease are to some extent mere guesses, for there is no ground for fixing its time of beginning and the earliest data attainable are only indications of disease already considerably advanced. The earliest and most frequent sign of malignant disease is the hæmorrhage. This may occur, as in Case 2, after sexual intercourse or it may be evidenced by increased bleeding at the menstrual periods. Loss of blood between the periods is common. When the discharge from the vagina has become foul, the smell will indicate that sloughing of the diseased surface has commenced and it is therefore a later sign. Pain is a late symptom of cancerous disease, yet it is all-important to the patient, for unless pain exists many patients do not seek advice and hence the reason why cases are so frequently discovered where the disease cannot be removed. When pain exists of a severe character, interfering with sleep and requiring narcotics for its relief, the disease will be found to have spread to the pelvic cellular tissue and peritoneum. It may be taken as proved (1) that the commonest age for uterine cancer is between forty and sixty years and (2) that it more frequently affects the lower ranks of society. Every patient who has had a loss of blood from the vagina after the cessation of the menstrual periods should be carefully examined, as this hæmorrhage may be the initial sign of malignant disease. Further, enlargement of the uterus after the menopause should always give rise to suspicion. It is supposed that the uterus becomes gradually smaller when its activity has ceased. This is true to a certain extent but in many women the process of involution is extremely slow, and when a large uterus is found where the menstrual flow has ceased the patient should be kept under strict observation. It is the exception to find cancer affecting the neck of the womb, where that organ is well involuted after the menopause. For the present we must collect the facts which clinical investigation furnishes, for as to the causation of cancer much has been written but little is really known. It may yet be proved to be a parasitic disease. I am a firm believer in the importance of gonorrhœal infection as a predisposing cause of cancer of the cervix, more especially where that infection leads to a chronic cervical gleet. Lacerations of the cervix are important not because they are the future seat of malignant degeneration, but because they are accompanied by thickening and enlargement of the cervix and body of the uterus from the absorption of septic products and thus predispose the tissue to malignant degeneration. Indeed, the septic subinvoluted uterus pouring forth a copious discharge from its cavity, so frequently found after abortion or full-time labour, especially among the poorer classes, is a most important factor in the causation of cancer.

In conclusion I must add one word of warning as to scraping the diseased surface. Such an operation in the early stages will only increase the growth and do more harm than good. As soon as the disease is diagnosed the proper treatment is early and complete removal. I always recommend total extirpation of the uterus because this allows the broad ligaments to be removed close to the pelvic walls. If this is not done I fail to see the advantage possessed by this operation over that of supra-vaginal amputation.

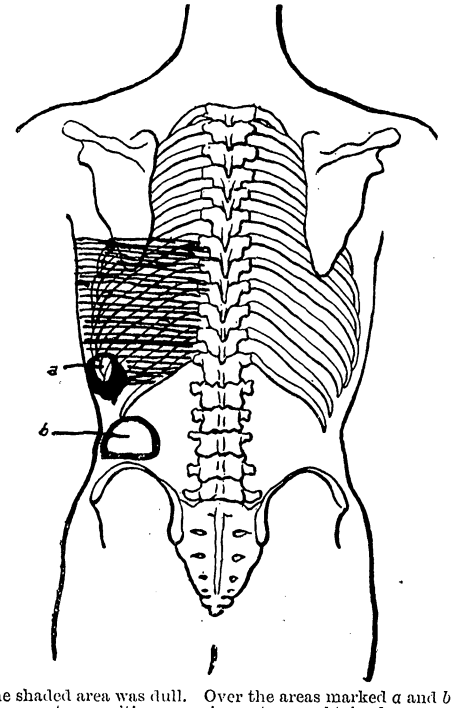
A CASE OF CANCER OF THE PYLORUS PRESENTING SOME UNUSUAL FEATURES.

BY J. MICHELL CLARKE, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GENERAL HOSPITAL AND PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, BRISTOL.

THE patient was a man, aged sixty-one years, who had worked for fifty years as a miner. The family history was unimportant and he had had no previous illness with the exception of being bruised by falling stones and of being burnt some years ago. He came to the hospital on May 22nd, 1894, and stated that the present illness began one week after Christmas quite suddenly with "cramp in the bowels." This shortly afterwards left him and except for an occasional twinge of pain in the abdomen he remained well until a month previously, when the pain again came on suddenly and was attended with swelling of the bowels; the pain was now more severe than before and was aggravated by food. He had been sick once only, on May 13th, after a cup of tea. The onset a month previously was attended with diarrhœa and abdominal tenderness and the diarrhœa returned again for one day a week previously to admission. The pain was excruciating, paroxysmal, and "doubled him up." There had never been hæmatemesis, melæna or hæmaturia, nor, so far as he knew, fever. He had not had jaundice. He could not account for the illness but had wanted sufficient food lately and had suffered much exposure. His appetite was lost; the bowels were regular. The pulse was regular but weak and empty between the beats. The arteries were thickened and tortuous. The respirations were 30. His sleep was disturbed by pain. The temperature was normal. The tongue was large, flabby, and coated with a moist brown fur. During the month he had been able to take very little food and had lost flesh. He was anæmic and emaciated and had an anxious expression. What at once attracted my attention when he walked into the out-patient room was a very large and localised swelling of the epigastrium which was quite evident through his clothes. On examination there were signs of pulmonary emphysema, the chest being barrel-shaped and hyper-resonant in front, and the cardiac dulness was obscured by the lung; the lower ribs on the left side were remarkably bulged out by the epigastric swelling. The heart dulness began above at the third space and ended below at the upper border of the fifth rib, where the percussion note became tympanitic. The cardiac impulse was at the sternal end of the third left intercostal space. Posteriorly, dulness on the left side began at the seventh rib and the lower angle of the scapula, and the breath sounds and the vocal resonance were absent over this area. Air entered the upper part of both lungs freely; the breath sounds were generally harsh over the whole of the right lung. Liver dulness extended 4½ in. in the nipple line; from the fifth rib to the lower costal margin its lower edge could not be felt; the liver dulness ended abruptly in the middle line at the right border of the tympanitic swelling. The epigastric and upper part of the umbilical regions of the abdomen were greatly distended and the flanks and the lower part of the abdomen were hardly distended at all. There was a tympanitic percussion note over the swelling extending upwards to the junction of the ensiform cartilage with the sternum in the middle line to the fifth rib in the parasternal line and to the left as far as the anterior axillary line at the level of the seventh rib; to the right it extended as far as the line joining the nipple with the middle of Poupart's ligament on the right side. Midway between the umbilicus and the ensiform cartilage the abdomen measured 35½ in.; and at the umbilicus it measured 31 in. There was dulness in the left flank; elsewhere the abdomen was resonant. The superficial abdominal veins were greatly distended. Over a small area at the end of the eleventh rib on the left side a tympanitic percussion note was obtained. No change was observed in the shape of the tumour when the patient sat up or in the area of dulness in the left flank. Nothing could be felt over the epigastrium owing to the extreme distension and no tumour could be made out in any other part of the abdomen. The urine was normal; the feet were bluish in colour but there was no œdema. The patient was unable to lie on his right side. On the 23rd the area of tympanitic resonance extended higher on the chest—i.e., as far as the fourth rib; there seemed to be more marked bulging of the ribs in the left hypochondrium; the area of tympanitic resonance at the tip of the eleventh rib had disappeared. Puncture with an exploring syringe in the left eighth intercostal space merely withdrew a little sanguineous fluid. On the 24th the left side of the chest was more bulged and was dull all over at the back, the heart beat to the right of the sternum in the third space, and the mediastinum was pushed over to the right. Two pints of sero-purulent fluid of peculiar opalescent appearance were removed by aspiration; this opalescence was perhaps due to the presence in it of a very large number of leucocytes which were crammed with fat-droplets as if they were undergoing fatty degeneration. Next morning the patient breathed more easily, was in less pain, and felt better. The abdominal swelling remained unchanged. On the 26th it was noted that the right side of the chest moved more freely than the left and that the cardiac impulse was in the third left intercostal space close to the sternum, but could also be indistinctly felt to the right of the sternum. The cardiac area began above at the third rib and ended below at the fifth. The bulging of the lower ribs on the left side and of the epigastrium was the same. The areas of dulness and tympanitic resonance are shown in Fig. 1. The transition from one to the other

FIG. 1.



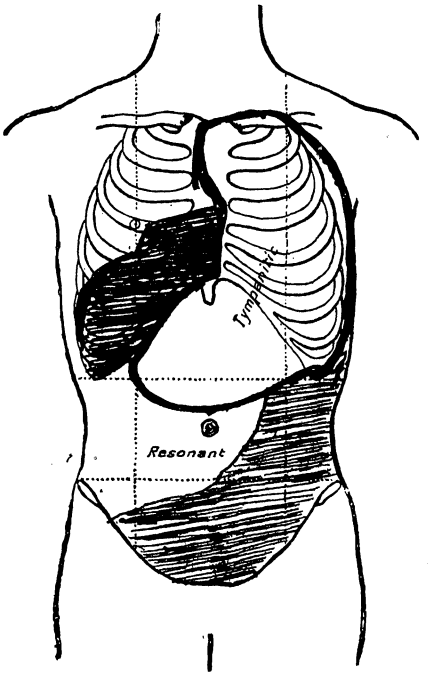
The shaded areas were dull. The circle marked *a* defines the area over which a bell-sound was obtained. The thick black line marks the outline of the stomach. The dotted line marks the shifting of the limits of dulness when the patient lay on his right side.

was quite abrupt except over the lower limit of the epigastric swelling, where it was ill-defined, the right side and the lower parts of the abdomen having now become more distended and yielding also a high-pitched tympanitic note on percussion. Over a circular area in the epigastrium a metallic tinkle was heard and the bell-sound was fairly distinctly obtained. In the sitting posture the areas of tympanitic resonance were unaltered except that dulness extended ½ in. higher over the left false ribs and a line of dulness 1 in. in breadth appeared along the lower border of the epigastric swelling just above the umbilicus. When he lay on his right side the left margin of tympanitic resonance in the chest was encroached upon for about 1 in.—i.e., moved 1 in. to the right. On the left side of the chest in front there were dulness, absence of breath-sounds and of vocal resonance below the

Digitized by Google

third rib (above this the note over the chest was somewhat tympanitic) and posteriorly below the fifth rib. The dulness in the left loin had now increased and a fluid thrill could be obtained between the loin and the epigastric swelling. When lying on his right side the anterior edge of the dulness in the loin shifted 3 in. further back and an area of tympanitic resonance of the size of a five-shilling piece appeared over the end of the tenth rib. Later in the same day this disappeared and a fresh tympanitic area appeared just above the middle of the right iliac crest behind (Fig. 2.)

FIG. 2.



The shaded area was dull. Over the areas marked *a* and *b* a tympanitic percussion note was obtained.

The temperature was normal. On the 28th the left side of the chest was found to be full of fluid, which consisted of thin pus, and the temperature had risen to 100·6° F. After consultation with my surgical colleagues it was decided not to open the abdomen but to evacuate the pus in the left pleural cavity by a free incision. This was done and three pints of thin pus were removed. The next day the wound was discharging freely; the temperature was 102°, the pulse was 96, feeble, with a tendency to dicrotism, and the respirations were 28 to the minute and laboured. There were all the signs of pneumothorax over the left side of the chest. The epigastric swelling had slightly decreased, the abdomen being at this part 32½ in. in circumference. The tympanitic resonance here was continuous with that over the left side of the chest (Fig. 3). There was dulness, shifting with the position of the patient, over the whole of the left side and the lower part of the abdomen. On the 30th the patient was very much worse, there was general abdominal tenderness, and the dulness over the lower part of the abdomen extended to a point 1 in. above the umbilicus. The signs were otherwise unchanged. The respiration was very difficult, at times gasping, the pulse was very weak, and he was obviously failing fast. He gradually sank and died on June 1st. After May 28th his condition was such as not to admit of any attempt at operative interference.

Necropsy.—At the post-mortem examination, twelve hours after death, the tympanitic areas on the chest and the abdomen were observed to be the same as during life. The left pleural cavity was full of air but contained no fluid. The stomach was very greatly distended but lay upwards and to the left, occupying the left epigastric region, its lower edge being at the level of the lower border of this region; it extended under the left lower ribs, pushing up the diaphragm to the level of the fourth rib in the nipple and anterior axillary lines. The tympanitic area was due entirely to the stomach and distended transverse colon which lay immediately below it. The heart was pushed over to the right. The pericardium was normal. The right lung was normal; the left was collapsed with the exception of the apex; its lower lobe was carnified. There was slight general peritonitis; the abdominal cavity contained about two pints of turbid fluid. With regard to the stomach, at the pylorus there was a firm mass of scirrhous cancer completely surrounding it, which where largest was about 1½ in. thick. There was no ulceration but here and there under the mucous membrane were some minute hæmorrhagic extravasations. A mass of hard, pale white retro-peritoneal glands, infiltrated with cancer, lay behind the stomach and just above and around the pancreas; this mass appeared to have prevented the descent of the dilated stomach. The pancreas was not involved. No perforation was anywhere found. Secondary cancerous deposits were numerous in the liver, but none could be seen in the left pleura or on the peritoneum. The other organs were healthy.

Remarks.—The case presented at the time considerable difficulty in diagnosis. The great distension of the epigastrium effectually prevented the palpation of the tumour. In obstruction at the pylorus from malignant disease the greatest degree of dilatation of the stomach is met with. As a rule the dilated stomach passes downwards and is not rarely so much distended that its lower border reaches to the pubes. In this case the stomach passed upwards and to the left and was at the same time pushed forwards by the mass of new growth behind it, hence the great protrusion of the epigastrium and the pushing up of the heart. It will be noticed

FIG. 3.

The shaded areas were dull. Over the area included within the thick black line there was a tympanitic percussion note.

that the area of stomach resonance took, roughly, an hour-glass form and that the lower border of the part behind the left ribs did not extend lower than the upper border of the eighth costal cartilage. Doubtless this portion of the tympanitic area was modified in shape by the presence of fluid in the left pleural cavity. The physical signs thus somewhat resembled those produced by a collection of gas and pus beneath the diaphragm. In both affections the lower part of the normal cardiac dulness becomes tympanitic; in the case just related this was due to the pushing up of the diaphragm by the distended stomach. As a subphrenic pyopneumothorax lies above the left lobe of the liver and pushes it downwards, whilst a distended stomach pushes it upwards, the determination by percussion of the position of this lobe should be of diagnostic importance, but in practice the dulness due to the left lobe is replaced by the tympanitic

Digitized by Google

note of the stomach or gas-containing abscess cavity. The fact that the area of tympanitic resonance extended so far to the right was certainly in favour of a distended stomach, but at the time, when viewing the whole features of the case, this did not come out so prominently as on after consideration. Dr. Ewart[1] lays stress on the occurrence in subphrenic pneumothorax of an irregular area of tympanitic resonance at the left base of the thorax posteriorly, whilst a distended stomach has a definite convex outline to the left and does not pass into the back. In my case, however, the small area of tympanites beyond the stomach to the left over the tenth and and the eleventh ribs was difficult to account for. Unless, as above suggested, it was due to the mass of new growth behind the stomach no satisfactory reason was found post mortem to explain why the dilated viscus did not descend into the abdomen in the usual way. Lastly, the making of a free opening into the left pleura was undoubtedly a mistake and by causing pneumothorax hastened the fatal termination.

Clifton, Bristol.

CASE OF INTRA-PERITONEAL RUPTURE OF THE URINARY BLADDER; ABDOMINAL SECTION; SUTURE; RECOVERY.

BY H. LITTLEWOOD, F.R.C.S. ENG.,
SURGEON TO THE GENERAL INFIRMARY, LEEDS.

SUCCESSFUL cases of suture of the urinary bladder after intra-peritoneal rupture are still of rare occurrence; their rarity and the direct saving of life as the result of an operation make cases of this kind of the greatest interest. The method of treatment adopted in this case was very similar to that carried out in other successful cases. Catgut sutures were used and it was never necessary to pass a catheter after the operation. One of the most important factors in obtaining a successful result in cases of this kind and in all intra-peritoneal catastrophes is undoubtedly an early diagnosis. In this case the operation was performed within 36 hours of the accident.

A man, aged twenty-eight years, was first seen by Mr. W. A. Stott at 10.30 P.M. on Nov. 28th, 1897. The patient went home at about 11 P.M. the previous night and could give no account of himself. He was intoxicated and his clothes were very muddy on his arrival home. He complained of a good deal of pain in the body throughout the night and the following day, at 10.30 P.M., he was seen by Mr. Stott, who made the following note: "Some abdominal tenderness and signs of fluid in the peritoneal cavity. Pulse 88, soft; respiration 18. Catheter passed and 2 oz. of urine withdrawn. Patient says he has not passed urine since the previous night." The next day, at 10 A.M., he was again seen by Mr. Stott. There was then some abdominal tenderness. Fluid could easily be detected in the peritoneal cavity and 1 oz. of urine was withdrawn by catheter; the temperature was normal and the pulse was 100. The diagnosis of an intra-peritoneal rupture of the bladder was made. I saw the patient half an hour later, agreed with the diagnosis, and at once made preparations for abdominal section. The operation was commenced about 11 A.M. Mr. J. Nicholson gave ether and Mr. Stott and one of my dressers—Mr. A. Spong—assisted me at the operation.

Operation.—An incision about 3 in. long was made in the middle line just above the symphysis pubis. On opening the peritoneal cavity a large quantity of fluid was found. It was a little turbid and obviously urine. The quantity was not measured, but estimated between 3 and 4 pints. This was rapidly emptied by means of sponges. Some coils of bowel which were seen were inflamed and between some of the coils there were present some flakes of purulent lymph. The rent in the bladder was soon found; it was in the middle line, about 1½ in. in length, and terminated just at the peritoneal reflexion from the top of the bladder. The opening was now easily brought near the surface and closed by means of eight or ten catgut sutures No. 0, by Lembert's method, including all the vesical coats with the exception of the mucous membrane. The vesical wall was thick and appeared quite healthy. It was not thought necessary to test the stitches by distending the bladder. The peritoneum was then carefully sponged, a Bantock's tube was placed in the pelvis, and the abdominal wound was closed. The operation lasted about one hour and the patient did not appear at all collapsed after it.

As to the after treatment, Bantock's tube was emptied frequently during the first twenty-four hours, the quantity of fluid rapidly diminishing, and it was removed at the end of the first forty-eight hours. It was never necessary to use a catheter, as the patient passed urine within six hours of the operation and continued to do so without any difficulty at regular intervals. The temperature was normal after the operation with one exception—on the evening of Dec. 3rd it reached 99·6°F. The patient never had a bad symptom; although there was some peritonitis at the time of the operation there was no further development of it after. The patient got up at the end of the third week and since then he has been quite well. He was shown at the clinical meeting of the Leeds and West Riding Medico-Chirurgical Society in March, 1898.

I have to thank Mr. Stott for kindly giving me the notes of the case before and after the operation.

Leeds.

ONE HUNDRED AND THIRTY CASES OF RINGWORM OBSERVED IN THE SKIN DEPARTMENT OF UNIVERSITY COLLEGE HOSPITAL, LONDON.

BY GEORGE PERNET, L.R.C.P. LOND., M.R.C.S. ENG.

SOME fifty years ago Grüby,[1] a Viennese doctor, settled in Paris, called attention to the parasitic nature of ringworm of the scalp and beard, and demonstrated the fact that the various clinical forms met with in practice were due to microscopically distinct fungi. Owing to the nomenclature adopted by him and to the opposition of the Parisian dermatologists of that period, Grüby's excellent observations appear to have been practically completely forgotten until Sabouraud[2] (1892 and onwards) published the results of his exhaustive investigations, which have been the starting point of so much work in this and other countries. It is not necessary here to once more go over the ground covered by previous English writers on the subject in the light of recent research. For full details the reader is referred to their publications.[3] Shortly, the present views with regard to the fungi causing ringworm are that they are divided into a small-spored (microsporon Audouini) and a large-spored (trichophyton megalosporon) form. The latter is further subdivided into two classes depending on the situation of the fungus inside (endothrix) or outside (ectothrix) the hair. To these an endo-ectothrix form is added by some. The main object of the investigation undertaken in the Skin Department of University College Hospital was to ascertain whether these researches were of any practical value as far as treatment and prognosis were concerned. The method pursued was to note the clinical appearances and there and then microscopically examine diseased hairs, stumps, and scales in liquor potassæ B.P. (i.e., about 6 per cent.). In this paper I propose to give a succinct account of the results

Digitized by Google

of the inquiry, which extended from October, 1896, to May of the present year. It must be understood that they apply to ringworm as observed in the practice of a London hospital.

The 130 cases under discussion were distributed as follows:—

	Small-spored (i.e., microsporon Audouïni).	Large-spored (i.e., trichophyton megalosporon).	Totals.
Tinea tonsurans	78	2	80
Tinea tonsurans associated with tinea circinata	18	2	20
Kerion of scalp	—	2	2
Tinea circinata	11	11	22
Tinea circinata (involving the scalp)	3	—	3
Tinea sycosis	—	3	3
			130

Of the 100 cases of tinea tonsurans and tinea tonsurans associated with tinea circinata, the microsporon Audouïni was present in 96 and the trichophyton megalosporon in 4—that is, 24 to 1. These proportions are, of course, approximate only, as they must necessarily vary within limits. Moreover, the 100 cases recorded did not represent all the cases attending the department during the period mentioned; for various reasons some few patients escaped examination. They may, however, be taken as fairly consecutive. These figures, agreeing on the whole with those of other London observers, show that the very great majority of our cases of ringworm of the scalp are caused by the small-spored fungus. With regard to the sex of the microsporon patients, the males were to the females practically in the proportion of 2 to 1. As the greater number of the children were of school-age, this difference in the incidence of the disease may be accounted for by the rougher play of boys, the more frequent interchange of head-gear among them, and the fact, too, that they wear the hair short. The oldest child was twelve years of age. In about a fifth of the cases of tinea tonsurans due to the small-spored fungus, tinea circinata lesions of the body were also present. The 4 cases of large-spored tinea tonsurans were distributed as follows: two boys, both aged thirteen years, and two girls, aged seven and eight years respectively. In the two girls tinea circinata of the body was also present; one of these patients really first came to the department in 1894; her out-patient's letter was renewed in 1897 as the disease was still uncured. The large-spored trichophyton was also found in the two cases of kerion. Both the patients were girls, aged five and eleven years respectively. As to the cases of simple tinea circinata they were practically evenly distributed among the small and the large-spored fungi. One adult, a woman, aged thirty-two years, exhibited the microsporon Audouïni (*vide infra*), and three adults (two women, aged thirty and forty-two years respectively, and one man, aged fifty years) the trichophyton megalosporon. I have placed three cases of tinea circinata in a separate division. They will be referred to under microsporon Audouïni. The three cases of ringworm of the beard (tinea sycosis) in which fungus was found belonged to the large-spored group.

MICROSPORON AUDOUÏNI: TINEA TONSURANS, INCLUDING THE CASES IN WHICH TINEA CIRCINATA WAS ALSO PRESENT.

Clinical.—In the untreated cases the diseased areas were circular, more or less scaly, sometimes densely so, dry, with bent, broken, twisted hairs from $\frac{1}{10}$ to $\frac{1}{4}$ of an inch in length growing usually in various directions. Exceptionally the short diseased hairs were quite straight, in one instance going off to a point, like an inverted note of exclamation, whilst others in the same patch were bent at an obtuse angle. The diseased hairs were usually whitish, opaque, with a powdery sheath about their base. This sheath was well marked in a case with a history of three years' duration. In an early case (a boy aged five years with two patches noticed one week) there was scaliness only, but no powdery spore-sheath at the base of the characteristic bent and broken hairs. As a rule the patches were multiple, well-defined, and not inflamed, but slightly reddened only. Many deviations from the type were observed, either as a result of long duration, or previous treatment, &c. In a boy aged six years with multiple patches of twelve months' duration the diseased hairs were whitish, dull, and curled up like wool. In previously treated cases the powdery spore-sheath was often absent. Rarely small bald areas were noticed; in other cases, again, the disease involved nearly the whole of the scalp. One of the latter looked very much like eczema seborrhoicum when first seen. Where tinea circinata was associated with tinea tonsurans the parts affected were usually the face and neck, more rarely the trunk and upper limbs. The patches were sometimes numerous, as in the case of a boy, aged nine years, with tinea tonsurans of the right parieto-occipital region, who had two small scaly patches on the forehead and about a dozen small, pale, fawn-coloured lesions with slight scaly borders about the body. In another, a girl, aged six years, with well-marked, densely scaly patches on the occiput, there were upwards of a score of circinate lesions scattered about the arms and the back of the neck. The majority of these were from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in diameter, well defined, but solid; the others were in distinct rings, the largest fully 1 in. in diameter.

Microscopical.—It is important in all cases always to select diseased hairs or stumps. These should be placed on a slide with a drop of liquor potassæ B.P., and the coverslip gently applied. Where ointments or oily applications have been used it is advisable to first get rid of the fat by placing the specimens in a little ether. (These remarks apply to the large-spored cases as well.) The characteristic feature of the small-spored fungus was the sheath of spores which surrounded the hair for some distance. This spore-sheath extended upwards beyond the intra-follicular portion of the hair. The spores were closely aggregated and fairly equal in size. They were not arranged in any special order, and in this differed from the endo-mycelial spores of the trichophyton megalosporon. They were units crowded together, in this way giving rise to a mosaic appearance. Detached single spores, and spores in twos, threes, and in clumps were seen away from the hair, especially when the coverslip was gently pressed down on the preparation. They were then seen to be round. After a time the spore-sheath having been loosened and the spores scattered, the delicate non-sporulated mycelium could be seen within the hair running more or less parallel with it. Where the root-sheath, or part of it, came away with the hair, which was not often the case, the spore-sheath was seen to be situated between the inner root-sheath and the hair itself. The large ghost-like elements mentioned by Adamson[4] were once noted, but the abundant segmented and sporulated mycelium observed by Fox and Blaxall[5] was never seen. A terminal fringe of mycelial threads towards the root-end was sometimes observed, and was probably due to the intra-pilar mycelium being torn away from the portion of hair left in the follicle. In very early patches of tinea tonsurans mycelium was found in the epidermal scales before the hairs were affected. In one instance abundant branched, granular mycelium (for description of the mycelium see tinea circinata *infra*) was present in the scales detached with hairs removed from a patch two days old. In the case of one of the hairs there were numerous spores for some distance up and outside the broken proximal end. In another, a couple of mycelial threads were seen penetrating it at the root-end nearly at right angles to the cross section.

TINEA CIRCINATA.

Clinical.—The lesions due to the small-spored fungus were either small, insignificant, pale scurfy patches, or distinct rings. One or two examples of the latter will be sufficient in this place. In a girl, aged seven years, there was a patch under the left jaw forming a distinct ring with nearly clear centre; she had a similar lesion near the umbilicus. (Her brother, aged three years, seen on the same day, had small-spored ringworm of the scalp.) A woman, aged thirty-two years, who had been bringing her child, aged five and a half years, for diffuse microsporon tinea tonsurans, developed three well-defined circular patches on the flexor surface of the left forearm. They commenced as small irritating pimples which enlarged and spread peripherally. The rings had a raised scaly border and showed signs of slight inflammation. The central portions were depressed and in the case of the two larger patches (nearly half an inch in diameter) scaly. Abundant mycelium of the small-spored kind was found in the scrapings. In three cases in which characteristic small-spored tinea tonsurans was also present some of the circinate lesions exhibited two concentric rings, one within the other. In infants ringworm of the scalp leads, as is well known, to circinate lesions and these may be due to microsporon Audouïni. This appearance was also

[4] Adamson: Loc. cit., p. 210.

[5] Colcott Fox and Blaxall. (British Journal of Dermatology. Loc. cit., plate II., fig. 4).

Digitized by Google

noted in a boy, aged seven years, who had a distinct ring on the left temple. It was about 2½ in. in diameter, with a slightly red margin, extending quite back into the hairy scalp, the anterior portion alone being on the free skin. There was abundant typical mycelium in the scrapings; mycelium was also present inside one of the broken, bent scalp hairs, but there were no spores outside it. The patient had been using oleate of copper ointment for ten days.

Microscopical.—Microsporon Audouïni in ringworm of the glabrous parts was present as coarse and irregularly branching mycelium, varying slightly in diameter and greatly in length and shape. The branching usually occurred laterally at right angles to the main filament and the branches were rounded in a spheroidal manner at their free end. (Morphologically, there are some points of resemblance between some of the mycelial elements of achorion Schönleinii (favus), microsporun furfur (tinea versicolor), and microsporon Audouïni as they occur in the human skin.) Further, the mycelium of small-spored ringworm exhibited small refractile dots here and there, which gave it a granular appearance, but it was not sporulated and was usually unsegmented.

TRICHOPHYTON MEGALOSPORON: TINEA TONSURANS.

Clinical.—As already stated, four cases only came under observation. The clinical appearances were much less uniform than in the case of the small-spored fungus. The patches were not so well defined and appeared to develop more slowly. As a rule they were smaller, varied more in shape, and were but slightly scaly. The stumps were few and far between and required careful looking for. They were, as a rule, broken off short very near or at the level of the scalp, in the latter case presenting the appearance of black dots. They did not exhibit a powdery sheath. The following descriptions from the notes made at the time may be referred to here.

CASE 1.—The patient was a boy, aged thirteen years. The duration of the disease was three months. Several small patches were scattered about the scalp. One in the occipital region was elongated, oval, and almost smooth. 2 in. higher up there was a ¼ in. scaly patch with a single stump covered by epithelial scales and broken off level with the scalp. In the left posterior parietal region there was a ¼ in. totally bare patch. The original patch on the left parietal was about 1¼ in. by 1 in. and ill defined; the stumps were very short, almost level with the skin, and very few in number. On the remaining parts the healthy hair was scanty.

CASE 2.—The patient was a boy, aged thirteen years. The duration of the disease was said to be 14 days (the fact is, the patient, who was dirty and neglected, did not know). There had been no previous treatment. The scalp on the left side, in the posterior half, was to a considerable extent bald. The denudation was incomplete and at the borders was distinctly patchy. Some outlying patches were from ½ in. to ¾ in. in diameter. The bald area exhibited here and there a certain amount of ill-nourished but not markedly diseased hair. On the parts which were almost bald there were a few black dots scattered about. There were stumps broken off short, very slightly if at all elevated above the level of the skin, and when removed they were about $\frac{1}{10}$ in. long. A few projected $\frac{1}{10}$ in. or more above the surface, but generally broke off when an attempt at epilation was made; a few other hairs were removed and were ¼ in. long and slightly curved. Several of the patches were reddened and very slightly crusted, like a subsiding kerion. There were also several bald areas about the scalp, slightly scaly and ill defined. In many of these no stumps could be seen.

Microscopical.—The characteristic feature of the trichophyton was the sporulated and segmented mycelium, or, in other words, the arrangement of the spores in chains. The spores were usually larger than those of microsporon Audouïni, but there was much variation in this respect. In Case 2 (*vide supra*) there were numerous spores forming a sheath round a stump; many were not larger than the spores of microsporon. There was sporulated mycelium inside the hair. Another stump had a few spores external to it. At the broken root-end and in the hair there were chains of spores, the latter varying very much in size, some being very large; higher up the mycelium was not so markedly sporulated; some, indeed, was not sporulated at all. This appearance led me to conclude that the fungus belonged to the ectothrix group, although there was mycelium in the stumps themselves.[6] The chains of spores, whether inside (endothrix) or outside (ectothrix), were arranged more or less longitudinally to the diseased hair and the individual spores were more or less square in shape. Where the mycelium was fragile the scattered spores were more oval and rounded. Of the four cases Cases 1 and 2 above described were apparently ectothrix (neither of these was associated with tinea circinata) and the other two were apparently endo-ectothrix (both had in addition tinea circinata patches).

KERION.

Microscopical.—Two cases only of kerion of the scalp were seen. The patients were girls, aged eleven and five years respectively, and in both large-spored fungus was present. In the latter case the segmented and sporulated mycelium were distinctly ectothrix, but in the former it was apparently confined to the internal portions of the diseased stumps examined.

TINEA CIRCINATA.

Clinical.—Usually the patients exhibited distinct rings with well-marked, raised, red scaly borders. The appearances varied from case to case, especially in the adults. A woman, aged thirty years, had a well-defined patch on the back of one hand. It was slightly papular at the border and somewhat depressed and scaly in the centre. She complained that the back of the hand swelled two or three times a day and became red. When the borders were scraped for examination there was a little serous exudation. Another woman, aged forty-three years, came with a patch 4 in. in diameter on the left forearm. It was papular and papulo-vesicular at the periphery, with here and there small sero-pustular lesions. A man, aged fifty years, had a patch over the knuckles and back of the left hand. The greater part was only reddened, but there were slight excoriation and crusting at the periphery.

Microscopical.—The large-spored fungus in tinea circinata was present in the form of jointed, long, usually straight, dichotomously branching mycelium, which was sometimes sporulated here and there. The segments varied in length, being shorter the nearer they were to the sporulation stage. The width also varied, the filaments being at times very slender. In the case of a male child, aged two years, with tinea circinata of the left cheek, sporulated mycelium was lying curled up in the centre of flattened epithelium cells, arranged in irregularly concentric layers around it; this portion of the preparation was dark in contrast to the clear surrounding epithelium, even after half an hour's soaking in liquor potassæ. In the case of the woman aged thirty years, the mycelium appeared to be attenuated, but it was distinctly divided into equal fairly long segments. On the other hand, in the woman aged forty-two years, where there was marked inflammation, the joints of the mycelium were short and thick (sporulation).

TINEA SYCOSIS.

It is not necessary in this place to give a clinical description of the above well-known condition.

Microscopical.—The fungus was not always easy to find and more than one examination of many hairs was sometimes necessary. In the three cases where the search was successful the trichophyton was apparently of the ectothrix kind. Sporulation of the mycelium was the rule, the segments being short and thick.

ETIOLOGY.

Microsporon Audouïni.—In the case of small-spored tinea tonsurans it was usually stated to have been contracted at school or from other children of the same family or in the same house. In several instances the mothers were of opinion the disease had been caught at fever hospitals where the children had been patients (for scarlet fever, &c.). As this may be the fact—in some cases at least—it would be as well in those institutions to keep children suffering from ringworm apart from the others and to avoid the use of the same combs and brushes. No case could be successfully traced to animals.

Trichophyton megalosporon.—Attempts to trace the disease to animals were also unsuccessful. One of the patients suffering from tinea sycosis was a groom, who stated that some of the horses under his care had suffered from ringworm, but the animals could not be seen. In another case of tinea sycosis, the patient stated that his two birds (a canary and a

[6] Colcott Fox and Blaxall: British Journal of Dermatology, loc. cit., p. 296, et seq.

Digitized by Google

linnet) were losing their feathers apart from moulting, but no fungus could be found in the feathers subsequently brought to the department. The barber's brush was most likely the *fons et origo mali* in all three cases. In several of the large-spored cases of tinea tonsurans and tinea circinata in children the father was a cabman or a carman; some lived over stables. But this also applied to cases which were distinctly small-spored in character. Moreover, microsporon fungi in the horse and dog have been described. Ringworm in animals is apparently rare in London. Horses are better cared for in London than in Paris; this may perhaps account for the greater proportion of the large-spored cases in Sabouraud's statistics, assuming that their animal origin be correct.

TREATMENT AND PROGNOSIS.

The differential diagnosis of the large and small-spored fungi does not help us much in London. In the first place, nearly all our cases of ringworm of the scalp belong to the small-spored variety, which is admittedly difficult to cure as a rule, especially in hospital practice. As to the few large-spored cases of tinea tonsurans which come under observation some are very obstinate, a fact already noted by several writers,[7] and confirmed by results obtained at University College Hospital. Nor are treatment and prognosis in tinea sycosis modified by the knowledge that the condition is due to a large-spored fungus. Both the cases of kerion were caused by trichophyton megalosporon and ran the usual course. They could not be compared with kerion cases due to microsporon Audouïni. Tinea circinata of the glabrous skin is, as a rule, readily cured, be it of large- or small-spored origin, and need not detain us. Apart from this, however, the question of the plurality of ringworm fungi is an interesting one, but as the scope of this paper is of a practical nature theoretical considerations will not be dwelt upon.

Before concluding I wish sincerely to thank my teacher, Dr. H. Radcliffe-Crocker, not only for placing the cases and notes at my disposal, but for much kindly encouragement during the progress of the inquiry.

CONCLUSIONS.

1. In a general way my results agreed with those of previous London observers (*vide* foot-note 3). The clinical and microscopical descriptions of Grüby[8] and Sabouraud[9] were in the main confirmed. Some points, however, must be more particularly referred to.

2. *Small-spored ringworm.*—In the scalp the diseased hairs were usually found growing in various directions. In this I agree with Malcolm Morris and differ from Sabouraud, Adamson, and Colcott Fox, who state that they grow in the direction of the natural set of the hair. Small-spored kerion did not come under my observation. Adamson, Fox and Blaxall, and Morris have met with it in London. Opinions differ as to the mode in which the hair is attacked. I have seen the mycelium of the small-spored fungus invading a hair at its root end. This is not in accordance with Sabouraud. I agree with Adamson and Fox that the fungus is in the epidermis before the hairs are affected. It appears to me to be natural that it should be so; but Sabouraud and Morris hold a contrary opinion. The abundant segmented and sporulated mycelium depicted by Fox and Blaxall[10] was never seen by me in the case of microsporon Audouïni of the scalp. On the body the lesions were sometimes in distinct rings, with a well-defined border and somewhat depressed centre; moreover, the border was frequently decidedly reddened and even slightly inflamed. This also does not agree with Sabouraud's original descriptions. In the series under consideration small-spored tinea circinata was as frequent as tinea circinata due to large-spored fungi. The view generally held is that nearly all the cases are of the latter kind. In adults this is certainly the case, but not in children. Moreover, small-spored tinea tonsurans may be associated with multiple small patches and rings on the body and limbs, but this is a rare occurrence. This again does not agree with Sabouraud's rule. The microsporon form of scalp ringworm appeared to be more contagious than that of megalosporon origin. This agreed with Sabouraud's Parisian experience.

3. *Large-spored ringworm.*—In tinea tonsurans the diseased hairs are usually broken off at or near the level of the scalp, but occasionally they are found projecting beyond the level of the scalp. This form is not always readily cured. It may be very obstinate and resist treatment for several years, a fact already noted by other London observers (H. Radcliffe-Crocker, Aldersmith, and Fox), but which does not agree with Sabouraud's Paris experience. The clinical appearances both in the scalp and on the body vary. This polymorphism has been insisted on by Sabouraud and confirmed in the case of London. The two cases of kerion belonged to this group and so far confirm Sabouraud's view, but whether they were derived from the horse could not be ascertained; the father of one of the patients was a carman. In tinea sycosis the fungus is not readily found. It may escape detection altogether where suppuration is well marked and when repeated examinations of many hairs are not made. This is generally admitted. The varieties of trichophyton megalosporon (endothrix, ectothrix, and endo-ectothrix) could not always be differentiated with certainty by microscopical examination.

4. *Relative frequency of large- and small-spored tinea tonsurans.*—My figures—viz., 96 small-spored to 4 large-spored—agree closely with Adamson's (178 to 5). Morris states that microsporon Audouïni is responsible for about 90 per cent. Fox and Blaxall give from 80 to 90 per cent., taking *all* ringworms (scalp, body, beard).

5. *Etiology.*—In no single case was it possible to demonstrate an animal origin. Several of the cases of tinea tonsurans had apparently been contracted in fever hospitals.

6. *Diagnosis.*—The differential diagnosis of large- and small-spored ringworm could usually be arrived at on clinical grounds alone and nearly always confirmed by a microscopical examination.

7. *Treatment and prognosis.*—With regard to these two points it is practically "as you were," for the two reasons already given, viz.: (1) nearly all the London cases of ringworm of the scalp (which alone concerns us here) are small-spored, which are admittedly obstinate; and (2) of the remaining rare large-spored cases some are extremely resistant to treatment.

A CASE OF TYPHOID FEVER IN WHICH A FATAL ISSUE FROM EXTREME TYMPANITES WAS AVERTED BY PUNCTURE OF THE TRANSVERSE COLON.

BY J. W. DALGLIESH, M.D. DURH.

THE patient was a man, aged about thirty years. He was first seen by me on Sept. 29th, 1896, and had then been ailing for four days. He complained of severe headache, giddiness, lassitude, bleeding from the nose, free perspiration, and inability to sleep. His temperature was 103° F. His tongue was furred and injected. When he was admitted to hospital on Oct. 1st typical spots were seen on the abdomen and chest. On the 2nd there were tympanites and colicky pains. He undoubtedly had peritonitis. On the 4th vomiting and diarrhœa were present. On the 7th the tympanites was most extreme, displacing the heart and interfering with its action. The apex beat was well above, and to the left of, the left nipple. The pulse was very frequent, irregular in time and force, intermittent, small and short, and devoid of tension. The patient's countenance was drawn, haggard, and pinched, and there were stupor and picking at the bedclothes with muttering delirium. The tongue was dry, raw, and beefy. The temperature was 104·4° and he appeared to be sinking fast. The administration of turpentine by the mouth was useless. Opium had already aggravated the condition. The passage of a long tube up the rectum led to the most tremendous evacuation of typical pea-soupy fluid which was horribly offensive, but no relief was obtained. Could more be done? The transverse colon was beautifully delineated, running across the abdomen in a very distended state. I boldly pushed a Southey's trocar and cannula into it. On withdrawing the trocar much gas escaped with a loud hissing noise for two minutes. At once there was great

Digitized by Google

relief to the abdominal distension and the facial expression improved wonderfully. The temperature rapidly dropped to 100°, the pulse became less frequent, regular and stronger, the tongue became moistened, the delirium disappeared, and much flatus began to be passed from the anus. On Oct. 9th the abdomen was quite flaccid and the bowels acted six times, the patient sleeping well. The temperature was 98° and the pulse was 72. On the 14th the tympanites was beginning again, but the albumin had disappeared from the urine. There were fresh spots and a troublesome cough from bronchitis. On the 16th the hæmorrhage from the bowels weighed 4 oz. On the 17th the patient became suddenly cold and collapsed. Internal hæmorrhage was diagnosed. On the 24th there was a fresh crop of spots with a return of fever. A few more interesting features may be related. On the 30th at 4 P.M. a marked rigor occurred immediately after a glycerine enema. On Nov. 1st a fresh rigor was experienced in the early morning for which there was no obvious cause. There was no malarial history and no sign of suppuration or inflammation. On the 2nd there was a rigor in the afternoon immediately after the bowels had been moved naturally. The patient was now put on quinine in large doses, which had previously been taken without benefit, and the temperature at once became subnormal and remained so until he left the hospital, but for several days after the last rigor he vomited after each movement of the bowels. He left the hospital looking remarkably well, but whilst at the seaside in December he was attacked with phlebitis and thrombosis of both femoral veins. He was, however, quite well on Jan. 15th, 1897, and had resumed work.

The case was a very severe one from the first. The patient was most carefully fed and well nursed throughout and the severity of the symptoms and the number of complications and the relapse were apparently entirely due to the severity of the poison of the disease. The patient's temperature from Sept. 30th to Oct. 8th averaged about 102°; on Oct. 9th, 10th, and 11th it was normal; from Oct. 12th to the 21st it averaged about 101°; on Oct. 22nd it was normal; from Oct. 23rd to the 27th it averaged about 101°; on Oct. 28th and 29th it was normal; from Oct. 30th to Nov. 2nd it averaged about 101°; on the evening of Nov. 2nd it was 104·4°; on the morning of Nov. 3rd it was 97·0°; and, as already mentioned, it remained subnormal during the remainder of his stay in hospital.

Bloemfontein, Orange Free State.

VACCINATION AND VACCINATION MARKS.

BY JOHN LOWE, M.D. EDIN.

THE vaccination question has long been drifting into an apparently hopeless tangle, and now that a "conscience clause" has been passed in the new Vaccination Act without any machinery being provided for better informing the public, but leaving it to the teaching of the opponents of vaccination, the position becomes still more perplexing and will, it is to be feared, proceed from bad to worse. It is not cheering for two-thirds of the people of this country to find in their midst a one-third minority of unvaccinated people who assume the right of controlling all legislation and who, being themselves open to the ravages of small-pox, feel no compunction at the idea of spreading it broadcast among their neighbours. That they had some grounds in time past for their objections to vaccination is admissible, and indeed this was freely admitted by the Royal Commission on Vaccination. Henceforth it will be more prudent not to quarrel with the views of these objectors, but to "trim our sails and let old bygones be," and to use every means to meet their objections and prejudices. This can be done only in two ways: firstly, by rendering the operation absolutely harmless and painless, so that no possible exception can be taken to its performance, and, secondly, by fully educating the public in the knowledge of the freedom from pain and risk which it secures and of the enormous benefits which follow from it.

The use of calf-lymph has largely diminished the risks of vaccination and the possible objections to it, but it cannot be denied that much remains to be done before the operation is a perfect one. Lord Lister's suggestion in the House of Lords that the time is not far distant when a completely antiseptic mode of vaccination will be attained commends itself as a valid and wise reason for delaying compulsory legislation until this period arrives. Dr. Copeman's glycerinated vaccine is an important advance in this direction, but, as has been pointed out, it is still on its trial and admittedly does not fulfil Lord Lister's desideratum of a perfectly antiseptic operation. Although the sequelæ have been greatly modified by it, its incompleteness is shown by its leaving the vaccination marks or cicatrices which are, for some inscrutable reason, regarded by the Local Government Board as the essential proof of success. The marks are, however, I think, a palpable proof that the operation has been non-antiseptic. They show that the pustular or suppurative stage has been reached and that the febrile state has been intensified and general irritation set up in the system by the absorption of septic poison from the pustules.

Hence the question arises, Is this suppuration and its attendant blood-poisoning a necessary part of vaccination? To this question I should reply with an emphatic negative, although I am bound to admit that, for a reason to which I shall advert presently, there is no absolute evidence on the subject. The insertion of vaccine lymph into the system produces certain changes of which the outcome is the vaccine vesicle. When this is fully formed and filled with colourless liquid the process is, I take it, complete, and it is difficult to believe that the subsequent change of this fluid into pus and the absorption of septic matter can add anything to the protective influence of the vaccine. That any chemical substance added to the vaccine lymph can make the whole process of vaccination antiseptic is doubtful, and it does not appear how under ordinary conditions, when a vesicle has fully formed, it should fail to go on to the formation of pus, except by direct antiseptic measures applied to the vesicle itself. For more than twenty-five years I have always used a plan of this kind. By means of a fine camel-hair brush a solution of pure carbolic acid is applied to the vesicle on the seventh or eighth day, the surrounding skin having been previously oiled with salad oil. A few seconds after the application tepid water is poured over the spot and a piece of antiseptic wadding is applied and strapped on lightly. The scab separates without a trace of suppuration and therefore without leaving the faintest cicatrix. Long ago I published this plan, but was met with the unanswerable argument, from the public vaccinator's point of view—"Without the cicatrix there will be no grant." Then there was the obvious suggestion that the protective influence of the vaccine may have been diminished by the treatment. I do not believe this. One might as well contend that small-pox treated as it has been by me in the same way was no longer small-pox, but some milder and less protective malady. It is, however, a question requiring examination and full investigation, and the time has come for this to be done, as I have long been sure it must come.

Some years ago, in speaking to a prominent member of the Royal Commission on Vaccination on the subject, he suggested that I should make these investigations, which in a certain degree are experimental though perfectly harmless, requiring only a revaccination after a stated period. I have made endeavours to carry them out with the result that the authorities refuse "to allow any experiment to be made in a public institution." One cannot quarrel with this decision, but it seems a pity that so simple a thing cannot be done, and one is disposed to wonder how Dr. Copeman's great improvement or Lord Lister's suggestion could be carried out without an equal amount of experiment.

The Local Government Board's insistence on the importance of the cicatrix is, I think, illogical. The work of the inspector consists mainly of examining these marks in a certain number of cases taken at haphazard from the public vaccinators' books, and on these the money grants for excellent results are founded. But it would certainly be as easy and much more satisfactory—supposing the antiseptic process to be adopted—for the inspector to pay a surprise visit on a vaccination day. He would then see not only how the cases which had been vaccinated during the previous week had succeeded, but also how the antiseptic provision on the eighth day was carried out. Surely, this would be a more satisfactory inspection than a glance at a scar and one which would give a much better idea of the character of the work done.

DOUBLE EMPYEMA FOLLOWED BY RECOVERY.

BY W. H. COOKE, M.D. BRUX.,
LATE RESIDENT MEDICAL OFFICER, THE ROYAL UNITED HOSPITAL, BATH.

DOUBLE empyema is so rare that I think the following case may be of interest. The patient was a girl, eleven years of age, who was admitted to the Royal United Hospital on Sept. 14th, 1896, her illness having commenced on the 11th with pain in the abdomen and vomiting. On admission she looked acutely ill and had a flushed face, marked dyspnœa with orthopnœa, and a rather tuberculous aspect. Her temperature was 102·6° F., the respiration was 40 and shallow, and the pulse was 114. There were signs of pneumonic consolidation together with friction at the right base. Three days after this friction and signs of consolidation were present at the left base also. The respirations rose to 66 per minute, the pulse to 160, and the temperature to 105°. There were considerable distress and continued crying out from the pleuritic pain. On Sept. 24th signs of fluid at both bases were present, the heart's apex being in the fifth space immediately outside the nipple line. On the 30th the left side of the chest was explored with a syringe and pus was withdrawn. On the next day an incision was made in the ninth space and a soft indiarubber tube was inserted, whereupon much flaky, sweet pus escaped. On the following day the pleura was washed out with 1 in 80 carbolic solution. On Oct. 6th, pus having been discovered on the right side by means of a small exploring syringe, an incision was made in the ninth space and an indiarubber tube was inserted. From this side also a large quantity of "laudable" pus escaped and the side was washed out next day. I regret to say that the pus was not examined microscopically. At both operations the A.C.E. mixture was administered and no unfavourable symptoms occurred. Both sides were washed out daily with iodine water until Oct. 30th, when the tube on the right side was removed and that on the left side on Nov. 9th. On Nov. 25th the girl was up and about; she was putting on flesh rapidly, both wounds having healed up. The temperature was normal and there was no deformity of the thorax, but at both bases there was a want of resonance, together with distant breath sounds which were probably due to thickened pleuræ. The heart's apex came back to its normal position.

From Sept. 14th to 20th inclusive the patient's temperature varied between 100·4° and 103·8°, with the exception that on the evening of the 17th it was 105°. From the 21st to the 28th inclusive it varied between 98° and 101°, with the exception that on the evening of the 25th it rose to 102° and on the evenings of the 27th and 28th to 101·6°. From the 29th to Oct. 13th inclusive it varied between 98° and 102·4°, with the exception that on Oct. 7th it was 97·4° at midday and 103·4° in the evening. On the 14th it varied from 97·6° to 100·6°. From the 15th to the 21st inclusive it varied from 97° to 100°, with the exception that on the 17th it was 100·2° and on the 19th 101·2°. From the 22nd to the 25th inclusive it varied from 97·4° to 99·6°. From the 26th to Nov. 15th it varied from 97° to 99·4°.

It will be admitted, I think, that double empyema is extremely rare—in fact, this is the first case which I have seen during twelve years' connexion with hospitals. Walshe, in his "Practical Treatise on Diseases of the Lungs," writes: "Cases of double empyema are, as a general rule, unfit for operation unless evacuation be rendered necessary for the prevention of asphyxia." Treves, in his "System of Surgery," vol. ii., p. 441, writes: "Double empyema is a very grave condition and, happily, not common. The two sides should not be opened at the same operation, but an interval of a few days or a week should elapse between the two operations." He concludes thus: "It is a striking and apparently a paradoxical fact that an operation (opening both pleuræ) which, if performed on the healthy, would be invariably fatal in its effects is a valuable means of saving life when employed in conditions of disease." That this child should have recovered in the way in which she did was a great surprise to me, for her condition on more than one occasion was extremely critical.

Bath.

A CASE OF ACCIDENTAL OVERDOSE OF CHLOROFORM.

BY EDWARD LAWRIE, M.B. EDIN.,
LIEUTENANT-COLONEL, I.M.S.; RESIDENCY SURGEON, HYDERABAD (DECCAN).

THE events now described took place between 8 and 9 A.M. on June 9th, 1898, at the Afzulgunj Hospital. The patient was a male native, thirty-six years of age, upon whom an operation was to be performed for cario-necrosis of the lower jaw. He had not had any food since 6.30 A.M. Immediately before the operation his pulse was found to be 128 per minute and weak; his respirations were 28. The chloroformist was Mr. Hamid-ud-Din, a third-year student of the Hyderabad Medical School. The notes were taken by Lieutenant-Colonel Lawrie until anæsthesia was complete.

Administration commenced in one-drachm doses on a cap as follows (the figures give the hour with the minutes and seconds):—

H.	M.	S.	
8	23	15	Cap applied, natural breathing, patient told to blow into the cap if he had a feeling of being choked.
8	24	0	Chloroform added to the cap; one breath of air taken.
8	24	55	Patient struggling, but breathing regularly.
8	25	0	Chloroform added to the cap; one breath of air taken.
8	25	50	Patient spitting.
8	26	0	Chloroform added to the cap; one breath of air taken. Patient struggling very violently but breathing regularly and deeply.
8	26	45	The patient was struggling so violently and taking such deep inspirations that although they were regular the chloroformist was told to remove the cap and give nothing but air. The patient took three full breaths of pure air and the cap was then reapplied.
8	27	10	Chloroform added to the cap. Two breaths of air taken. The patient became quiet and began snoring before the cap was reapplied.
8	27	25	Cornea insensitive; the cap removed. (It was never put near the face again. The notes were now taken by the assistant house surgeon.)
8	28	0	The patient's breathing stopped suddenly; his eyes were staring, his pupils were widely dilated, and his skin was pallid. The surgeon sprang on to the table and, kneeling astraddle the patient, commenced artificial respiration. The chloroformist pushed forward the patient's lower jaw and opened his mouth, and the house surgeon pulled out his tongue. There was great delay and difficulty in doing this as the teeth of the right half of the lower jaw were all loose, and there was a piece of loose dead bone. Another assistant poured some nitrite of amyl on to a handkerchief and held it over the patient's face, while the artificial respiration was going on, in such a way that it was freely inhaled.
8	30	40	Natural breathing restored. Artificial respiration stopped.
8	32	30	Consciousness returning.
8	35	15	Operation finished. Patient walked out of the room.

In this case the overdose was taken in during the struggling stage, which was due to intoxication, the breathing being quite regular. Overdosing with regular breathing, even if it be abnormally deep, is the rarest form of chloroform accident which is met with clinically, and it is more than ordinarily dangerous because the regularity of the respiration puts the chloroformist off his guard. The fault in the administration consisted in not at once giving the patient more air when the struggling became violent and the breathing abnormally deep. At 26 minutes 45 seconds past 8 o'clock when the chloroformist was told to give the patient air alone—because it was evident that he was inhaling the chloroform too freely—the cap should not have been reapplied until the breathing became normal and it was known

Digitized by Google

whether the anæsthesia was becoming deeper or not. The mechanism of the action of an overdose in a case like this is explained on page 17 of the Hyderabad Commission's report: "(2) If the inhalation (of chloroform) is interrupted at any stage the fall of blood-pressure continues at a rate which altogether depends on the rapidity of the fall while the chloroform was being inhaled. This afterfall is probably due to absorption of a portion of the residue of chloroform in the air passages after the stoppage of the inhalation. In this way it often happens, if chloroform is given rather freely (more especially if there has been struggling and deep inspirations), that though the respiration is going on when the chloroform is discontinued it afterwards stops."[1] The restoration of the patient was effected by artificial respiration and the artificial inhalation of nitrite of amyl, and the rapid recovery after natural breathing had recommenced was probably due to the beneficial action of this drug.

Hyderabad.

A SIMPLE AND EFFECTUAL METHOD OF STERILISING CATGUT.

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS, AND PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY.

A GROWING sense of the superiority of readily absorbable material such as catgut for ligatures and buried sutures, if only one could be sure of its absolute asepticity, and the acknowledged uncertainty of the commercial preparations, led me to make some experiments on the effect of heating catgut in substances other than water with the view of determining whether after heating for some time to a temperature of 100° C. it would still be sufficiently strong to be employed as a suture or ligature. At first, I used methylated spirit which was heated in a cylinder made for me by Messrs. Down Brothers and specially prepared to withstand the pressure under which spirit would be when subjected to the temperature of boiling water. The results obtained were satisfactory, the catgut after being heated in alcohol for twenty minutes being quite as strong as before heating. This substance was given up only because it was considered inadvisable to run the risk of an explosion if some fluid equally suitable in other respects could be obtained which had a boiling-point higher than water. Three substances were selected: aniline, the boiling-point of which is 184·5° C.; xylol (di-methyl-benzene), which boils at about 140° C.; and glycerine, the boiling-point of which is above 100° C. and which at ordinary atmospheric pressure decomposes before it reaches its boiling-point. Trials with each of these three substances left the catgut strong, but on the whole xylol has been found to give the best results, and, indeed, when it is used the result is better than with methylated spirit, the catgut shrinking, gaining in strength, and "biting" better when tied. For some time I have used catgut, usually the "00" size, prepared in this way and have had every reason to be satisfied with it. At the outset the ordinary dry chromic carbolic catgut was used, but recently I have employed ordinary unmedicated catgut with equal satisfaction.

The exact method adopted is the following. The catgut is wound *loosely* from end to end round an elongated glass reel made for me by Messrs. Reynolds and Branson of Leeds. Several of these glass reels are then introduced into a metal cylinder, the cap of which screws on, and after more xylol than is sufficient to cover them has been poured in the cap is adjusted. The whole is then put into the boiling water in the steriliser and allowed to remain along with the instruments for from 20 minutes to half an hour. After being thus sterilised the reels with the catgut which has shrunk round them are removed *at once* and kept either in 5 per cent. carbolic acid solution or in methylated spirit, the latter being preferable, as any aqueous solution tends to cause cutgut to swell. In this solution they may be kept on the reels till required. I have kept them as long as five weeks without any diminution in the strength of the gut, but I ordinarily prepare the catgut at the same time and along with the other instruments before each operation. After each heating the cylinder should be dried and the used xylol rejected, as a certain amount of decomposition takes place and catgut will soften if heated in it a second time. Care should be taken that no water is allowed to mix with the xylol, or of course the catgut will gelatinise.

The great advantage of this method of sterilising catgut lies in its simplicity and the ease with which it can be carried out, while, judging from clinical results, especially those in which unmedicated gut was used, the sterilisation seems to be absolutely complete. I have to thank my friend, Dr. Farquhar Macrae, for his kind assistance in carrying out the numerous experiments which had to be performed before arriving at the perfected method which I feel that I can fully recommend to other operators.

Leeds.

[1] It must be remembered that in all the experiments of the Hyderabad Commission chloroform was administered very freely in order to test the effects of overdoses.

VAN ERMENGEM'S METHOD OF STAINING FLAGELLA: A MODIFICATION.

BY J. W. W. STEPHENS, M.B. CANTAB.,
JOHN LUCAS WALKER STUDENT, UNIVERSITY OF CAMBRIDGE.
(*From the Pathological Laboratory, Cambridge.*)

VAN ERMENGEM'S solutions consist of: 1. Osmic acid, 2 per cent. solution, 1 part; tannin, from 10 to 25 per cent. solution, 2 parts; to each 100 c.c. add from 4 to 5 drops of glacial acetic acid. 2. Gallic acid, 5 grammes; tannin, 3 grammes; fused acetate of soda, 10 grammes; distilled water, 350 c.c. 3. Nitrate of silver, from 0·25 to 0·57 per cent. solution.

The method of using these solutions can be found in most elementary text-books of bacteriology. With care precipitates can be avoided and clear, well-stained flagella shown. But at other times, and especially in class work, thick deposits of silver result and very few, if any, flagella are shown. To careful workers, also, with this method failures are by no means unknown. The modification which, in my hands, has given beautiful results consists in using instead of nitrate of silver one of the many compounds of silver and albumin now on the market. I was led to try one of these compounds as it is stated of them that they are not precipitated by chlorides or albumin. The particular compound used by myself is "largin," which contains over 10 per cent. of silver. This body smells of ammonia and when dissolved in distilled water forms a clear brown solution. Chlorides give a mere trace of precipitate. I follow exactly the usual procedure, using as my silver bath a 2 per cent. largin solution, which will contain about 0·2 per cent. of silver. The actual times in each particular solution after the mordant are of little importance and the film may be passed back and fore from silver to gallic acid three or four times or oftener. If this method be tried it will be noticed that a greyish film is formed on immersing in the gallic solution after previous immersion in the silver solution. On replacing in the silver solution this film is dissolved up and the cover-glass is left perfectly clear, the silver solution taking on a deep mahogany colour, but no precipitate forms in the silver bath. The film has thus passed through (1) largin (from 2 to 10 minutes), (2) gallic acid (from 2 to 10 minutes), (3) largin (till clear), (4) gallic acid again if necessary, and so on back and fore. These details may be varied at will—e.g., the film may be rapidly washed in water between each bath (or the film may even be blotted); it is well to drain off excess of silver before putting in the gallic acid bath, but these are points which each observer can easily find out for himself, the "condition" of the cover-slip being the important matter.

In preparing the cover-glasses they should always be burnt on a piece of wire gauze to remove all fat. The case and certainty with which well-stained, clean preparations can be obtained by this method have induced me to publish this brief note in order that others with time at their disposal may find out by trial the best strength of "largin" solution to use and whether "protargon" or other similar bodies could equally well be used. I have stained so far in this way the typhoid bacillus, Gärtner's bacillus, bacillus fluorescens, vibrios, and micrococcus agilis (the latter showing extremely long flagella with large open curves). It is quite possible that an ammoniacal solution of silver nitrate would give the same result, but this I have not actually tried.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON A CASE OF SACRO-ILIAC DISEASE.

BY ARCHIBALD W. CUFF, B.A., B.C.CANTAB., F.R.C.S.ENG.,
ASSISTANT SURGEON TO THE CHILDREN'S HOSPITAL, SHEFFIELD.

THE serious nature of tuberculous disease of the sacro-iliac joint has long been recognised, but its comparative rarity and the failure, until within the last few years, of operative measures devised for the relief of its later and more severe forms, may perhaps invest the record of the following case with some interest.

A youth, aged eighteen years, came under my care in May, 1897, complaining of pain in the lower part of the back and inability to walk. He had first experienced pain over the sacral region eight months before, and this had been getting worse. With the increase of the pain came a sense of weakness in the left lower limb and an inability to bear much weight upon it. Three weeks before I saw him a swelling had been noticed to be present over the region of the sacro-iliac joint. The patient's father and mother had died from phthisis. The patient was very thin and appeared to be in much pain. All the classical signs of disease of the sacro-iliac joint were present. Severe pain and sense of weakness were present in the sacral and gluteal region. The former was made worse by movement and by pressure on the iliac bones. Manipulation of the hip showed that joint to have perfect movement, although owing to the severity of the neighbouring lesion it caused pain in spite of my endeavour to immobilise the pelvis. The lameness, the inability to walk, and the alteration in the shape and the apparent length of the limb were well marked. The glutæi were wasted, as were also the muscles of the limb. An oval swelling, with its long axis almost vertical and about four inches in length, was present over the position of the left sacro-iliac joint. This swelling fluctuated and was obviously an abscess. The diagnosis of left-sided sacro-iliac disease was made and the operation devised by Collier and Golding-Bird was performed for its relief. Under an anæsthetic I raised in a forward direction a large semi-lunar flap, consisting of skin, fascia, muscle, and posterior ilio-sacral ligament, and having thoroughly exposed the bone I proceeded with a half-inch trephine to remove a crown of bone from the neighbourhood of the base of the inferior posterior iliac spine, just above the upper border of the great sciatic notch and immediately over the joint. In raising the flap the abscess, which overlay the joint beneath the muscle and fascia and which communicated with the joint by a sinus, was opened, and its wall was afterwards scraped and cut away. A probe passed into the sinus went into the joint, passing between the iliac and sacral surfaces to do so. On removing the circular crown of bone the joint was opened in its lower part. A distinct though small cavity containing granulations and minute fragments of bone and pus was present. The contents of the cavity were removed with a scoop and with the gouge and mallet the surrounding diseased portions of bone were excised. The disease appeared to have spread laterally, involving the ilium, rather than upwards, and it was confined chiefly to the lower part of the joint. Having removed as far as possible all the morbid material and otherwise cleansed the wound the flap was replaced in position and secured with silkworm gut stitches. Up to the first dressing at the end of a week all went well and the incision seemed to be healed, but at the second dressing tuberculous nodules appeared in the line of incision and in the flap and a collection of opalescent fluid beneath it. The diseased portions were again cut and scraped away and the wound was plugged with iodoform gauze. Iodoform emulsion was injected into the wound every two or three days and the plugging was repeated. The wound steadily but slowly healed. The patient was kept lying in bed with a long outside splint on the diseased side for several months and then allowed up in a wheeled chair. The pain and lameness disappeared and in January, 1898, he resumed his work as a cutler. I saw him in the last week of August. I found him free from any trouble and in good health. A depressed, painless, firm scar, semilunar in shape, marks the site of the operation. The pelvis seems to be perfectly firm though from the amount of bone removed at the operation I had considerable doubts as to its future stability.

Sheffield.

A CASE OF SEPTIC PERITONITIS; LAPAROTOMY; RECOVERY.

BY H. W. MILLS, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a strong, well-nourished woman, aged about forty years. There was a history of gonorrhœa many years ago. I had attended her on and off for some eighteen months previously for attacks of pelvic peritonitis, a pelvic abscess forming and discharging each time *per vaginam*. On the present occasion she had treated herself by rest in bed and hot douches, expecting the usual termination to her trouble. Such, however, did not occur; on the contrary, the pelvic abscess broke into the general peritoneal cavity and septic peritonitis resulted. When I saw her she was lying on her back in bed with her knees drawn up. The abdomen was greatly distended; low muttering delirium and constant retching had been present for twenty-four hours. The temperature was 103° F. and the pulse was 140. *Per vaginam* the cervix was felt high up and the uterus was fixed as if in plaster of Paris. There was bulging in the posterior and lateral fornices, especially in the left. On the following day, chloroform having been administered, I opened the abdomen in the middle line. The abdominal walls, omentum, and superficial coils of intestine were densely adherent, and the latter were with some difficulty separated sufficiently to admit three fingers into the general abdominal cavity. On withdrawing the fingers several quarts of brownish, very offensive fluid containing large thick flakes of lymph escaped and subsequently about a pint of evil-smelling brown pus. The upper part of the abdominal cavity was partly, at any rate, shut off by adhesions. The abdominal cavity was thoroughly irrigated with boiled water, the peritoneum was plugged with iodoform gauze, a tight binder was applied and the patient was put back to bed in a collapsed condition. She rallied, however, after a hypodermic injection of strychnine and an enema of hot, strong coffee and brandy. For several weeks her condition was critical, intestinal obstruction threatening on several occasions. The wound was dressed twice a day after the first twenty-four hours, the cavity being irrigated with boric acid lotion and later with lotio sodæ chlorinatæ, and subsequently replugged with iodoform gauze. A considerable amount of pus continued to escape for several weeks. Hypodermic injections of morphia had to be repeatedly given during the first three weeks after the operation for the relief of pain and for the troublesome and persistent attacks of retching. Eventually the discharge became serous and finally it stopped, the cavity contracted, and the abdominal wound granulated up. The patient made an excellent recovery and is now, a year after the operation, in the best of health.

Ruardean.

NOTE ON A CASE OF OXALIC ACID POISONING; RECOVERY.

BY F. J. LORIMER HART, M.B., C.M. EDIN.,
ASSISTANT SURGEON, HOME AND INFIRMARY FOR SICK CHILDREN, S.E.; DIVISIONAL SURGEON, METROPOLITAN POLICE.

I WAS recently summoned to a case of attempted suicide and taking the stomach syphon-tube and hypodermic case I arrived within twelve minutes after the poison had been swallowed. I was shown a "tumbler" to the sides and bottom of which were clinging rather less than one and a half drachms of undissolved crystals having the taste and appearance of oxalic acid. The patient, a lad, aged fifteen years, was unconscious; his skin was markedly pallid and clammy and his extremities were cold. No pulse could be felt at the wrist. The pupils were fully dilated and his lower jaw was fixed in tetanic spasm, froth exuding between the teeth. He was said

Digitized by Google

by the friends to be just recovering from a strong convulsion. I injected one-tenth of a grain of apomorphia hypodermically. The stomach syphon-tube was then passed after levering the lower jaw open and upwards of a pint of warm water was introduced into the stomach. This was almost immediately expelled, no doubt by the action of the apomorphia. On a second attempt to pass the tube the patient began to struggle — consciousness having partially returned—and it was found impossible to wash out the stomach thoroughly. Vomiting, however, continued and the organ appeared to have been well evacuated. He had by this time sufficiently gained consciousness to be induced to swallow about half an ounce of powdered chalk suspended in water which was shortly afterwards ejected. With the aid of brandy, strychnine, and digitalis administered hypodermically he had recovered so as to be out of danger in two hours, the heart's action, however, failing several times during that period.

On inquiry I found that the lad had purchased half an ounce of oxalic acid from a local druggist and that the whole of this quantity had been used in making the solution, all of which he drank except what had remained undissolved. This made the quantity taken upwards of two and a half drachms. In a previous case of oxalic acid poisoning to which I was called the patient died within a quarter of an hour of swallowing the fatal dose. The quantity taken in that case was unknown, but was probably over half an ounce. According to Taylor, one drachm is the smallest quantity of oxalic acid which has been known to destroy life at the age of sixteen years, death occurring in eight hours. Under three minutes is given as the shortest known period of survival after an unknown quantity of this poison had been taken.

KING'S COLLEGE HOSPITAL.

A CASE OF CHRONIC GLANDERS; RECOVERY.

(Under the care of Mr. WILLIAM ROSE.)

IN THE LANCET of Sept. 24th we published the history of a case of glanders in which much difficulty was found in arriving at a correct diagnosis. In the following case the diagnosis was greatly simplified by the very definite history of the disease in several horses among which the patient had worked. In this case the infection had occurred at three widely separated spots and at each there was much tendency to spread locally, but no absorption of the poison and generalisation of the disease took place. The difficulty of removing all the local disease by scraping is well shown in the sinus in the leg, which continued to extend for more than a year after its first appearance. The general health of the patient suffered very little considering the extensive and long-continued suppuration, and the favourable result demonstrates that if by persistent operation the local poison can be removed complete recovery may ensue. For the notes of the case we are indebted to Mr. C. A. Sprawson.

A young man, aged nineteen years, was admitted into King's College Hospital on Feb. 8th, 1897, suffering from multiple abscesses. His previous and family histories were quite unimportant and no evidence of syphilis could be obtained. His habits were very temperate and by occupation he was a carman and a worker in stables. About a month before admission to the hospital an abscess appeared, according to the patient's account, on the left side of his forehead; for this he consulted a medical man. A fortnight later two other abscesses appeared, one on the extensor surface of the right arm and the other on the outer aspect of the right leg. The abscess on the forehead was opened and as the patient did not seem to improve he was sent to the out-patient department of King's College Hospital, where he was seen by Mr. Carless, and the next day he was admitted to the ward. When examined on admission he was seen to have on the left side of his forehead a wound resulting from the opening of the abscess; from it pus was still flowing and a "pocket" passed from it downwards beneath the skin. With a probe bare bone could be felt. This cavity was syringed out with solution of carbolic acid (1 in 40) and packed with iodoform gauze. The house surgeon, Mr. G. Atkinson, opened the abscess on the arm and dressed it similarly; it was shallow, but extended under the skin. On the peroneal aspect of the right leg was seen a tense fluctuating swelling nearly 5 in. long; it was extremely tender and was evidently a large abscess. The patient's general appearance was healthy; his temperature was normal on admission, but it rose to 101° F. on the following day. The urine was acid and contained neither albumin nor sugar. There was no discharge from the nose and at first the patient denied that he had ever had any such symptom, but later he acknowledged that during the three weeks preceding admission there had been a watery discharge from the nose, which at the time he attributed to an ordinary cold. The case was not thought at first to be one of glanders, but on the day after admission inquiries elicited that in his work as carman the patient had much to do with twelve horses, and that six weeks before admission six of these horses, one after another, developed swellings in the neck; they were seen by a veterinary surgeon and were killed. In his own mind the patient had never connected the disease of the horses with his own illness and none of his fellow workers seem to have suffered at all in the same way, though about three months earlier one of them had a wound of a finger which took a fortnight to heal. On Feb. 22nd Mr. Rose incised the abscess in the leg and evacuated some blood-stained pus; there was no bare bone; the cavity was packed with gauze. The abscesses were dressed daily; it was found necessary on two occasions to make a counter-opening for the abscess on the forehead, as there was much burrowing; when the first counter-opening was made some pus escaped and some of it was caught in a sterilised tube and sent to the British Institute of Preventive Medicine for examination; the report on this pus stated that though no bacilli were discoverable microscopically in this pus, yet when guinea-pigs were inoculated with it they soon developed the typical symptoms of glanders. By March 12th the temperature had become normal, the patient's general health was good, though he was somewhat troubled with night sweats, but the healing of the abscesses progressed very slowly, and on April 6th it was found necessary to lay open the leg further downwards owing to the burrowing of the abscess. On May 7th the abscess in the arm had nearly healed, but as the burrowing of the abscess on the forehead had increased, the skin between the three sinuses was cut through and the cavity well scraped with a sharp spoon. The sinus in the leg was treated similarly. At first the wounds seemed to improve after this treatment, but later they all continued to spread, and Mr. Rose laid them open again, scraped them, and swabbed them out with liquefied carbolic acid. Every third day after this the wounds were swabbed out with carbolic acid and soon began to look more healthy. On June 14th a note was made that the patient's general condition had not been so good lately; he complained of headache and pains in the back and at the same time he showed a distinct *tache cérébrale*. The wounds also commenced to burrow again; they were therefore once more scraped and wiped out with pure carbolic acid. The carbolic acid was used every other day and all the wounds improved greatly and by July 14th the arm was well. Towards the end of July an attack of pharyngitis caused a temperature of 103° for a few days, but the wounds continued to improve, so that early in August he was able to get about on crutches. The ulcer on the head was smaller, but still discharged some greyish pus, which crusted round the wound causing a peculiar appearance which had been noticed during the whole of the case. The sinus in the leg increased in length and on Sept. 1st Mr. Carless laid it freely open and applied carbolic acid to the interior. By Sept. 20th both wounds were looking better; the ulcer on the forehead had healed except for a patch as large as a sixpenny-piece. The burrowing of the sinus in the leg continued and on Oct. 30th Mr. Rose made a counter-opening immediately below the external malleolus, avoiding the peronei

Digitized by Google

tendons. Two further examinations of the pus were made. The first was negative in result, but the second showed the bacilli of glanders. The ulcer on the forehead healed by Nov. 17th, but the sinus in the leg required several other operations, as it had tracked downwards along the tendon of the peroneus longus, but fortunately the process was stopped before it reached the sole of the foot. Healing gradually occurred, but was not complete until the middle of June, 1898.

DORSET COUNTY HOSPITAL.

A CASE OF HERNIA OF THE APPENDIX VERMIFORMIS; OPERATION; RECOVERY.

(Under the care of Mr. WILLIAM ERNEST GOOD.)

ALTHOUGH it is by no means unusual to find the vermiform appendix in the sac of a femoral hernia—as, for instance, in hernia of the cæcum—yet it is certainly rare for the appendix to be the sole occupant of a hernial sac. It is not unlikely that in many cases it may form so slight a swelling that the hernia is not noticed, and if no strangulation takes place the hernia may never be suspected. In addition to the cases quoted by Mr. Good in his remarks we may mention the following. Langton describes a case in which perforation took place.[1] Keetley also had a case,[2] and L. A. Bidwell describes two cases,[3] in neither of which was the appendix strangulated. In a case recorded by W. McAdam Eccles[4] the hernia was found post mortem in a man who died from carcinoma of the stomach; the hernia had apparently given rise to no symptoms. It is somewhat strange that strangulation of the vermiform appendix should cause such severe symptoms as occur in some cases, for there is no obstruction to the onflow of fæces. It is of interest to note that in nearly all the cases the patient was a woman. It is possible for an appendicitis to occur in an appendix while lying in a hernial sac,[5] and it is not improbable that some of the cases thought to be suffering from strangulation were really cases of appendicitis.

A domestic servant, aged thirty-nine years, was admitted to the Dorset County Hospital on March 8th, 1895, with a tense swelling in the right groin. This had existed since the previous day, was accompanied with pain and vomiting, and presented all the appearances of an irreducible, strangulated femoral hernia. The patient having been placed under chloroform Mr. Good cut down on the tumour and on opening the hernial sac it was found to contain a portion of a strangulated and congested vermiform appendix. About 4 in. or 5 in. were drawn out of the wound and after some constricting tissue had been divided the finger easily traced the appendix into the right iliac fossa. It was unusually long, probably at least 7 in. A double ligature of carbolised catgut was applied and about an inch of the appendix was cut off; the ends of the ligature were left long as a drain and the stump was left in the wound, which was partly closed by silver wire. On cutting open the amputated portion the diagnosis of the hernia being that of the appendix was confirmed by the presence in it of a little greenish, feculent-looking slime. The patient made a tedious convalescence, but was discharged well on April 6th.

Remarks by Mr. GOOD.—Hernia of the appendix vermiformis is not common. Mr. Davies-Colley in an article in the Guy's Hospital Reports[6] gives particulars of two cases which occurred in his practice and one which occurred under the care of Mr. Durham, and another under the care of Mr. Clement Lucas, and refers to five others. Recently Mr. Newbolt of Liverpool has published a case[7] and refers to two others, one by Mr. Annandale and one by Mr. Jacobson.

WATER-SUPPLY OF CHARD.—Mr. F. H. Tullock, of the Local Government Board, held an inquiry at Chard on Sept. 20th relative to the application by the town council to borrow £2500 for works of water-supply. After a lengthened inquiry Mr. Tullock said that there was an obvious need for a proper water-supply for the whole town and added that this would have to be carried out. He also strongly commented on the inaction of the town council.

Reviews and Notices of Books.

Diseases of the Stomach. In Three Parts. By JOHN C. HEMMETER, M.D., Clinical Professor of Medicine in the Baltimore Medical College. London: H. Kimpton. 1898. Pp. xxvii. and 788. Price 30*s.*

Diseases of the Stomach: a Text-book for Practitioners and Students. By MAX EINHORN, M.D., Adjunct Professor in Clinical Medicine at the New York Post-graduate Medical School and Hospital. Second revised edition. London: Baillière, Tindall, and Cox. 1898. Pp. 486. Price 12*s.* 6*d.* net.

IT is significant of the attention now being paid to the subject of digestive disorders and also probably indicative of the prevalence of such maladies in the United States that the publication of an exhaustive treatise like that of Dr. Hemmeter should have been speedily followed by a second edition of Dr. Einhorn's text-book about a year after its first appearance. It is further evident that the endeavour to unravel the problems connected with gastro-intestinal derangements has been the source within comparatively recent times of much fresh knowledge upon the digestive processes. Thus there have been introduced many and more exact methods of examination of the functions of the stomach in health and disease which ought to have a practical application in the treatment of dyspepsia, the besetting malady of civilised mankind. Yet the actual gains to therapeutics due to these scientific methods and researches have been hardly commensurate with the trouble and ingenuity which have been bestowed upon them. To a certain extent they have only served to confirm the opinion formed of the value of old and well-tried measures introduced at a period when gastric chemistry was in its infancy, whilst many of the new methods which may be applied for diagnosis and treatment are so irksome to the patient that it will be long before they come to be universally applied, in spite of the rational basis on which they are founded. Nevertheless we cannot but welcome the insight given into the vital functions of the digestive organs by such patient investigations, with the assurance that every fact thus added to physiology and pathology cannot but have an important influence upon the true conception of these functions and the most appropriate measures to be taken to remedy their derangements.

Dr. Hemmeter's treatise comprises a thorough survey of the whole subject of disease of the stomach, and nothing is omitted which is material to its full comprehension. Indeed, if any criticism be allowable upon what has evidently been a most arduous and painstaking work, it would be that in some parts there is apt to be too much material, as, for instance, in the numerous diet tables which occupy the chapter on Dietetics. The author shows that he has a profound acquaintance with the abundant literature of the subject, and he certainly has brought his book quite up to date. It is, however, far from being a mere compilation, although there are not seldom copious citations, for Dr. Hemmeter has himself contributed not a little to the scientific investigation of gastric affections. The subject matter of the work is treated under three main divisions—namely, (1) Anatomy and Physiology of the Digestive Organs—Methods and Technics of Diagnosis; (2) Therapy and Materia Medica of Stomach Diseases; and (3) the Gastric Clinic. The description of the histology of the stomach is largely culled from the writings of Bensley and Mall, but the physiology of digestion is treated succinctly and more independently. This latter section comprises further the intestinal processes, where, by the way, we note the statement of the author that so-called intestinal disinfection is still "an unsolved

Digitized by Google

problem." Several methods for testing gastric peristalsis are described in a chapter devoted to this topic, the opinion being expressed that Ewald's salol method is unsuitable for private practice and that, moreover, the amount of salicyluric acid excreted in the urine by the use of this test, is considerably influenced by the blood-pressure. Klemperer's "oil" method and Fleischer's "iodoform" method are also described, as well as the ingenious mechanical instruments invented by Dr. Einhorn and by Dr. Hemmeter. The latter's "gastrograph" consists of a bag of the shape of the stomach which being introduced into the viscus is so adapted to its interior as to act as a recording apparatus of the latter's movements. The author considers that the motor function of the stomach is of the highest importance, for he thinks most of the disorders of secretion and absorption are to be attributed to defective motor activity. Several tracings (gastrograms) are given. The testing of the power of absorption and the means whereby the size and capacity of the stomach can be estimated are then described, including the ingenious method of "gastro-diaphany" which we owe to Dr. Einhorn. Ample information is supplied upon the use of the stomach tube, the practice of lavage and the several colour tests and other reactions upon the gastric secretion, and also there is an account of the examination of the gastric contents. In point of fulness this account leaves little to be desired. As already hinted, much consideration is given to the subject of dietetics which finds a place in the second part of the work. At the same time the author remarks, with justice, that there is no need to insist upon too harsh measures of restriction in most forms of dyspepsia. It is quite right for cooking to receive the attention here devoted to it, and many hints are given on the preparation of foods for invalids. The subject of alcohol and of the medicinal agents most in vogue in the treatment of gastric disease follows, whilst this portion of the work closes with an account of surgical intervention in organic disease. The third part of the book, which is devoted to the description of the various diseases of the stomach, opens with an account of gastritis, the author agreeing with Ewald and Penzoldt in discarding the term "catarrhal," and the pathology as well as the symptomatology of its various forms is amply discussed. The bibliography of the subject is most copious, and in addition to a lengthy list of authorities on the subject in general, more than four pages are filled with references to writings upon phlegmonous gastritis alone. Ulcer of the stomach is, we learn, associated with hyperacidity in 88 per cent. of cases and the etiology of the lesion is summed up as linked with one of four conditions—namely (1), impaired vitality or resistance of portions of the mucosa; (2) hyperacidity or supersecretion; (3) an altered state of the blood; and (4) local bacterial infection. So far as we could find, no mention is made of the view which has been forcibly put forward that the initial lesion of gastric ulcer is to be found in the solitary glands or lymphoid tissue. Indeed, the pathological anatomy of ulcer is not very fully treated in this work. Considerable space is given to malignant tumours and stress is laid upon the detection and examination of fragments of the mucosa in the vomit or washings of the empty stomach as an aid to diagnosis. The rare lesions of tubercle and syphilis are described from records in literature, and then follows an account of Benign Tumours. The subject of Motor Insufficiency and Dilatation is amply dealt with, and the same may be said of Enteroptosis and Gastroptosis, which are responsible for many ills and discomforts. The "Neuroses" are grouped under the heads of Motor, Sensory, and Secretory, and in each department it is claimed that there may be recognised states of excitation and states of depression of nervous influence. Whether the present state of knowledge is such as to enable the dyspepsias to be divided into the numerous conditions which can be assigned by such a division is questionable, but at any rate the scheme has the merit of being ideally complete, leaving but little room for any fresh additions to the list. We part from Dr. Hemmeter's work with the sense that it embodies the best knowledge of the time, that it is a book which is of inestimable value as a work of reference, and that it will well repay the most careful study which can be given to it. The index is remarkably complete.

Less ambitious in scope but covering the same field is the text-book of Dr. Max Einhorn. This book is more suitable for the practitioner but quite as abreast of modern inquiry as the larger treatise. Here, too, descriptions of methods of examination precede the detailed accounts of gastric disorders. The author's ingenious gastrograph (in some respects preferable to that of Dr. Hemmeter) and his gastro-diaphane are clearly described and their application in diagnosis is well brought out. Lavage and the "tests" of the stomach contents receive adequate and judicious treatment, whilst the amount of information which can be obtained by a careful microscopical examination of the washings of the viscus is a point worthy of the attention of all clinicians. The drawings of fragments of mucous membrane detached from the stomach, which show degenerative, atrophic, and neoplastic changes, are evidence of the value of the practice. The employment of the gastric douche and the use of direct electrisation of the interior of the stomach form new and valuable additions to measures of treatment, nor is their use difficult, as Dr. Einhorn plainly shows. We need not dwell at length upon the chapters dealing with the several morbid states, but it may be of interest to note how considerable is the space devoted to the secretory and other functional derangements which constitute the dyspepsias. In this department terminology is enriched by many new but not euphonious additions—"hyperchlorhydria," "gastrosuccorrhœa continua periodica" and "chronica," "achylia gastrica," and "ischochymia," the two latter denoting mainly the conditions formerly termed "gastric atrophy" and "gastric dilatation." Dr. Einhorn justifies the use of the term "ischochymia" on grounds which may be deemed satisfactory, for by it he implies a hindrance to the due emptying of the stomach, the stagnation of the contents of which is responsible for most of the symptoms of gastrectasia. There is a brief but sufficient account of enteroptosis and, finally, the nervous affections are succeeded by a chapter on Affections of the Stomach in other Diseases. The book is one which can be recommended for the clearness and conciseness with which the whole subject is treated and for its eminently practical character.

Tests and Studies of the Ocular Muscles. By ERNEST E. MADDOX, M.D., F.R.C.S. Edin. Bristol: J. Wright and Co. Pp. 427. 1898. Price 10*s.* 6*d.* net.

THIS work will be found to repay perusal. Without being of a controversial nature it is very suggestive and places many points in regard to the action of the ocular muscles in a new and interesting light. At the same time the author has contrived to give a valuable epitome of the work on this subject which has been done in this country and abroad, and especially in America, during the last few years. Many circumstances render inquiries into the functions of these muscles difficult. Their coördinated action is complicated and difficult to follow even under normal conditions, and in disease the difficulty is greatly increased on account of the symptoms being to a large extent subjective and therefore requiring close attention on the part of even the most intelligent patient.

The author commences with a short description of the ocular

Digitized by Google

muscles and their relations, which are exceedingly important, to the capsule of Tenon. In describing the actions of the ocular muscles he introduces some new terms which are useful since they abbreviate descriptions and are at the same time perfectly intelligible. Thus, the rotation of the cornea on its edge outwards like a wheel he describes as extorsion and the muscles which effect this—viz., the inferior rectus and inferior oblique—are termed "extortors," and so the muscles which rotate it inwards, the superior rectus and superior oblique, are intortors. He points out that the insertions of the several recti muscles form, as described by Tillaux, a kind of spiral, for beginning with the internal rectus and proceeding to the inferior external and superior recti in order they are attached at distances of 5, 6, 7, and 8 millimetres from the margin of the cornea. He endeavours to explain the existence of the pulley of the superior oblique by attributing it to the necessity of a contrivance for obtaining length, whilst its presence in association with the superior and its absence in the inferior oblique he believes to be due to our habitually looking downwards in our daily work.

The disposition and influence of the "check ligaments" are given in full detail and should be studied by all those who undertake to perform the division of the tendons of these muscles. A chapter is devoted to Motor Faculties, in which, without any particular novelty in their treatment, such subjects as the fixation of the eye, normal and abnormal projection, the perception of distance, and the stereoscope are dealt with. The succeeding chapters are devoted to Strabismus and Ocular Paralysis. In the treatment of the former the author quotes with approval Javal's course of treatment by means of regular exercise of the muscles. It must be acknowledged, however, that such exercises require great patience, that they take up a great deal of time, and are not always successful.

The eleventh chapter is devoted to Ophthalmoscopic Corneal Images and the mode of utilising them for the recognition of strabismus. Dr. Maddox gives a mode of ascertaining by means of the corneal reflexes whether or not a squint is paralytic which is of practical value. It is to this effect. The palm of the left hand should be laid on the patient's head with instructions to let the head follow the most gentle guidance of the hand without resistance. The exact position of the corneal reflex in the squinting eye is now to be noted, whilst the fixing eye is directed to the central aperture of the ophthalmoscopic mirror and the head is steadily moved in various directions. If the position of the reflection is unchanged the squint is concomitant; if it be changed the squint is paralytic. Priestley Smith's mode of strabismometry is described and the value of photography in the diagnosis of squint pointed out. We recommend Dr. Maddox's work to all who are practising ophthalmic surgery.

Atlas and Essentials of Pathological Anatomy. By Dr. O. BOLLINGER. In 2 vols. London: Baillière, Tindall, and Cox. 1898. Price 12*s.* 6*d.* each volume.

THESE two volumes form part of the Hand-Atlas Series published in German by Lehmann. In our previous notices of other volumes of the series we have commented on the excellence of the plates and the present numbers form no exception. The illustrations are most beautifully executed. The first volume deals with the Circulatory, Respiratory, and Digestive Apparatus, including the Liver, Bile Ducts, and Pancreas, and contains 69 coloured figures upon 60 plates and 18 illustrations in the text. It is impossible to speak too highly of the efforts of the artists and lithographers, nor would it be an easy task in the space at our command to draw attention to as many of the plates as we could wish; but we may mention as some of the best those depicting fatty degeneration of the heart muscle, chronic fibrous and calcareous endocarditis of the aortic valves, adenoma of the thyroid gland, diseases of the lung caused by inhaled dust, &c. The second volume considers the pathological anatomy of the urinary apparatus, sexual organs, nervous system and bones, and contains 63 coloured figures upon 52 plates and 17 illustrations in the text. In this volume again the various pathological conditions are reproduced with wonderful fidelity. Plate 10, showing a cystic kidney, and Plate 12, exemplifying chronic tuberculous pyelo-nephritis, are especially good.

At the end of each volume is a full account of the various pathological conditions figured arranged in a more systematic manner. The student will find this work a most valuable one as an aid to his pathological studies. It can hardly replace the ordinary text-books, but he will be well advised to add these volumes to his library and to constantly refer to them whilst reading his other medical and surgical works.

Atlas of Clinical Diagnosis and Internal Diseases. By Dr. CHRISTFRIED JAKOB. Authorised Translation from the German. Edited by AUGUSTUS A. ESHNER, M.D. London: The Rebman Publishing Company. 1898. 68 Plates and 64 Illustrations in the Text. Pp. 259. Price 12*s.* 6*d.*

THIS also is one of the Series of Hand-Atlases issued by the firm of Lehmann of Munich of which several have already appeared in English dress. The plan of the book consists in coloured plates containing in all 182 illustrations and in some text—which forms about one-half of the volume—treating of the methods of physical examination, and giving also a summary outline of internal diseases exclusive of those of the nervous system. The plates comprise microscopical drawings of the blood, sputum, and urinary deposits as well as the colour-reactions obtainable in testing the gastric juice and urine. Then come a large number of percussion outlines of normal and diseased conditions of the thoracic and abdominal viscera. All these figures are coloured and they tell plainly the conditions which they represent, and as they are all taken from actual cases, of which a brief outline is given on the page facing the diagram, they will be useful as guides to the clinical student in the art of graphic representation of clinical facts. Although such a book may not be really as useful as some of the other works in this series it affords a compendious insight into the methods of clinical investigation and should be welcomed as an addition to a field already occupied by many works of a more pretentious class.

Medical Diseases of Infancy and Childhood. By DAWSON WILLIAMS, M.D., F.R.C.P. Lond., Physician to the East London Hospital for Children, Shadwell, &c. London, Paris, New York, and Melbourne: Cassell and Co. 1898. 8vo. Pp. 626. Price 10*s.* 6*d.*

STUDENTS cannot complain of the lack of excellent manuals dealing with diseases of children. The latest, from the pen of Dr. Dawson Williams, will certainly not be the least popular among students and practitioners. Well arranged and clearly written, it embodies the experience of the author during many years at the Shadwell Hospital for Children. While indicating his own views very distinctly Dr. Dawson Williams gives adequate space to the teaching of others on points of pathology and treatment with which he is not fully in accord.

Commencing with a short chapter on the Hygiene of Infancy Dr. Dawson Williams goes on to give practical directions for the clinical examination and observation of infants and of older children. Diseases incidental to birth

Digitized by Google

are described, including such accidents as meningeal hæmorrhage from injuries during labour. A somewhat short chapter is given to the Feeding of Infants. Like most other authorities Dr. Dawson Williams recommends diluted raw cow's milk when its purity and freshness can be guaranteed. In other cases he gives directions for pasteurising or for absolute sterilisation. This chapter scarcely goes far enough, dealing only with feeding during the first six months and containing little guidance for the very important transition period before the child is fully equipped with teeth.

The section dealing with the acute specific fevers is very well done, particularly the chapter on Diphtheria, where there is an excellent concise account of the bacteriology of the disease and of the results of treatment with antitoxin. Curiously, however, no practical directions are given for the clinical bacteriological examination of a doubtful case. The statistics quoted show very conclusively the importance of giving antitoxin early, the mortality not being greatly reduced when it has been delayed till the fifth day of the disease.

Tuberculosis receives full attention and is followed by one of the best chapters in the book, that on Inherited Syphilis. Referring to the possibility of direct infection of syphilis by vaccination Dr. Dawson Williams believes that most alleged instances are cases of inherited syphilis and holds that "no case can be admitted to be an example of syphilis due to inoculation at vaccination unless a primary chancre be discoverable." The account of rickets is somewhat condensed for so important and common a disease.

Diseases of the various systems of the body are described shortly in their turn. A very full and well-illustrated account is given of the acute gastro-intestinal affections of infancy, including a full notice of the recent researches of Professor Baginsky of Berlin. Cretinism is well described, but there is little mention of other forms of mental defect the recognition of which in early life is often as important as it is difficult. Dr. Dawson Williams adheres to the restricted view of rheumatism as a disease of joints rather than a general condition. Although he puts the chapter on Chorea next to that on Rheumatism instead of among nervous diseases he is by no means clear that it is "merely a rheumatic manifestation." His chapter on Rheumatic Fever describes rheumatism rather as it occurs in the adult, but it fails to take account of the slight afebrile rheumatism so often seen in young children which has been so well described by Dr. Cheadle. The book is very complete, containing notices of rare conditions such as the hæmoglobinuria of the newly-born, and also excellent chapters on Malaria and Hydatid Disease, in which Dr. Manson and Mr. Twynam have coöperated.

The book is very well illustrated by reproductions of clinical photographs and photo-micrographs and there is a very full index. It forms a worthy member of the practical series published by Messrs. Cassell and Co., and its convenient size, its completeness, and the excellence of its teaching enable us to recommend it strongly as a trustworthy manual for students and practitioners.

LIBRARY TABLE.

First Aid to the Injured. By Dr. FRIEDRICH ESMARCH, being Six Ambulance Lectures Translated from the German by H.R.H. Princess CHRISTIAN. Sixth edition. London: Smith, Elder, and Co. 1898. Price 2*s.*—*First Aid to the Injured and Management of the Sick.* By E. J. LAWLESS, M.D. Brux., D.P.H. London: The Scientific Press, Limited. 1898. Price 3*s.* 6*d.*—Of these two little books the former is the more elementary, containing practically only such information as may be rightfully made use of by any bystander who has a head on his shoulders. Dr. Lawless's book gives drill instruction for stretcher-bearers and certain information as to field and camp hospitals. Professor Esmarch's book is written with all that emphasis and clearness which those who know that admirable work of his, "The Handbook for the Treatment of the Wounded in War," look for from him. There is only one point to which we take exception, and that is the statement upon page 31 as to the use of the carbolic spray in operations. Surely, this has been altogether given up. Otherwise we have nothing but praise for this work, and the section upon nursing is of special excellence. The translation, so far as we can tell without having compared it with the original, is well done—i.e., unless we knew it were translation we should not think it was. Dr. Lawless's book goes upon much the same lines, only it deals in addition to first aid with such subjects as instruction camps for volunteers, the duties of hospital orderlies as sick nurses, cookery for the sick, and the like. With regard to the making of coffee Dr. Lawless allows two teaspoonfuls of coffee to three-quarters of a pint of water. This may make an infusion suitable for the sick, but to call it coffee is a misnomer. On other points Dr. Lawless's book is admirable; more especially we may note the sections dealing with Life in Camp, How to Manage on the March, and the Appendix—Fresh Air and Ventilation.

Clinical Lectures on Diseases of the Heart and Aorta. By GEORGE WILLIAM BALFOUR, M.D. St. And., LL.D., &c. Third edition. London: Adam and Charles Black. 1898. Pp. 479. Price 12*s.* 6*d.*—Few words are needed to introduce this fresh edition of a well-known work to the notice of our readers. When the lectures first appeared twenty-three years ago they at once attracted attention from the style in which they were written, the wealth of clinical material they contained, and the sound doctrines they imparted. Dr. Balfour's reputation stands high in the department of cardiac diseases and medicine owes to him many valuable hints and wise reflections. The lectures, too, are just those which may have been given at the bedside. Each one is furnished with the records of cases which serve to illustrate the text and point to the enforcement of rules of treatment. The purely clinical descriptions are preceded by two lectures on Diagnosis, which convey in clear language the significance and theory of production of the various physical signs. Dr. Balfour treats of subjects which are most likely to lead to erroneous inferences, and none can peruse the lectures on Curable Mitral Regurgitation, on the Vanishing and Variation of Cardiac Murmurs, or that on the Simulation of Aneurysm without being instructed and assisted in practice. Indeed, this work is eminently suited for the careful perusal of the practitioner, who will gain from it much that is useful to him in matters of diagnosis and treatment, and will, moreover, be enabled to judge more accurately as to the probable course and duration of cases of valvular disease, and often, mayhap, to take a more hopeful view of their prognosis. For to arrive at a right judgment in any case of heart disease many points have to be considered and the least important frequently is the presence of a murmur. This and more is the lesson conveyed by Dr. Balfour's sensible teaching, based as it is upon years of observation and experience. We heartily welcome this new edition of a much valued book.

Rheumatoid Arthritis: its Pathology, Morbid Anatomy, and Treatment. By GILBERT A. BANNATYNE, M.D. Glasg., M.R.C.P. Edin. Second edition. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent and Co. 1898. Pp. 182. Price 7*s.* 6*d.*—The subject to which the author of this book has devoted much study is one that has long formed a sort of debateable ground amongst pathologists and clinical observers. Many and various have been the doctrines put forward to explain the etiology of this

Digitized by Google

slowly progressive, painful, and crippling disease that seems to occupy a place apart in nosology. Dr. Bannatyne himself is persuaded that the key to its pathology is to be found in ascribing it to microbic agencies, and strange as it may seem at first sight to refer a chronic disorder of this class to such a cause he makes out a fairly good case in support of his contention. Readers of THE LANCET are familiar with his views, and the fact that his work has reached a second edition is proof that his mode of presentation of the subject has been received with favour. The clinical portions of the book are well written, the salient facts and the variations met with being very systematically treated. Numerous illustrations, including some interesting Roentgen photographs, add to the value of the text. In point of treatment the author finds in the creasotes, phenols and naphthols remedies which act by virtue of their bactericidal properties and thus harmonises their employment with the pathological doctrines which he holds. The value of thermal treatment in the more chronic stages is insisted on and of this the author's experience of the Bath waters enables him to speak with authority.

Zig-Zag Ramblings of a Naturalist. By R. TAYLOR MANSON, L.R.C.P. Edin., M.R.C.S. Eng. Second edition. Darlington: William Dresser and Sons. 1898.—This is a collection of very charming essays dealing with the natural history of a portion of that country of which Kingsley so well says:

"The name of the place is Vendale, and if you want to see it for yourself you must go up into the High Craven and search from Bolland Forest north by Ingleborough to the Nine Standards and Cross Fell, and if you have not found it you must turn south and search the Lake Mountains down to Scaw Fell and the sea; and then if you have not found it you must go northward again by Merry Carlisle and search the Cheviots all across from Annan Water to Berwick Law; and then, whether you have found Vendale or not, you will have found such a country and such a people as ought to make you proud of being a British boy."

This country is perhaps fuller of romance than any other part of England, save possibly portions of Somerset, Gloucester, and Cornwall, and Mr. Manson writes as one who not only knows it but loves it. His derivation of the jeweller's "heart" charm from the flint arrowhead is certainly a plausible one, though we do not remember ever to have seen it noted before. In the chapter called "Our Park" Mr. Manson discourses pleasantly about the differences between the leaves of the beech, the elm, and the hornbeam. The leaf of the last-named is sometimes mistaken for that of the beech, but they are not much alike. Still there is often a difficulty in distinguishing between the leaves of the wych elm and those of the hornbeam, that is to say, unless they be examined together. Neither tree is very common in England, but there are twelve magnificent hornbeams at Temple Lock on the Thames, and there used to be, and we trust still is, a gigantic wych elm in the park at Magdalen College, Oxford. Both town and country dwellers should read Mr. Manson's essays, for both will, or should, profit by them.

New Inventions.

AN ANATOMICAL URETHRAL BOUGIE.

BOUGIES and catheters mapped out to correspond with the anatomy of the male urethra, so as to indicate the situation of strictures or other abnormalities, have been made for me by Mr. Alfred Cox of 108, New Bond-street. An ordinary bougie is encircled with a red line six inches from its extremity, which six inches when passed into the urethra inform the operator that the point of the instrument is about entering the membranous portion. The next three-quarters of an inch of the instrument is marked off with another red line, and as it is being passed the extremity of the instrument is making its way into the prostatic portion, after which the passage of the next marked part—viz., 1¼ in.—tells that the prostatic portion is occupied and that the instrument is about to enter the bladder.

RALPH STONEY, L.R.C.S. Irel., &c.
Gloucester-terrace, S.W.

THE SOUDAN CAMPAIGN.

(FROM OUR SOUDAN CORRESPONDENT.)

THE number of cases of sick and wounded under treatment in this hospital to-day is 139, of which 111 are cases of wounds, gunshot and otherwise, which may be classified as follows: gunshot, 78; sabre and spear, 17; and other wounds, 16. This does not include the 6 wounded officers. The other cases are principally fever (including a few enteric) and dysentery. On the whole, the wounded are doing very well and it is contemplated sending off a sick convoy to Cairo at an early date. The worst cases are those of gunshot wounds of joints, of which luckily there are not a great number. Up to date about 22 operations for the removal of bullets and the suturing of tendons, &c., have been performed, and, thanks to the x rays, the surgeon's work has been much simplified. As I stated in my last letter we have two excellent apparatus, one for a 10 in. spark and one for a 6 in., and they have proved of great service. The bullet wounds were nearly all caused by Remingtons and the amount of splintering of bone has necessarily been great, the only exception that I have noticed being the case of Lieutenant-Colonel Sloggett of the Royal Army Medical Corps; in his case the aperture of entry was one-eighth of an inch above the left nipple and that of exit in a direct line from before back, a little to the outer margin of the axillary border of the scapula. This wound was undoubtedly inflicted by a small-bore French or Italian rifle (to which, in my opinion, Lieutenant-Colonel Sloggett owes his life), as, with the exception of severe shock at the time, accompanied by a high temperature for a few days and slight dyspnœa, his symptoms have never been urgent and I am happy to say that he is gaining ground daily, the consensus of opinion being that the bullet undoubtedly perforated the chest and made its exit at the point described. The other wounded officers are doing well, though the sabre wound of Lieutenant Nesham of the 21st Lancers is a very severe one and had divided all the tendons of the wrist and the median and ulnar nerves. These have been successfully sutured. Of the amputation cases the one at the shoulder joint (for a railway injury) died from shock and exposure to the sun as the patient lay beside the line for some hours before he was discovered, and the only other case up to date, that of an arm at the middle third, is doing well. There is a rumour that the Red Cross Society have prepared a boat to take the wounded from Assouan to Cairo[1] and I can only hope that it is so, as they will benefit more by this route than by the intensely hot, jolting, and dusty journey by train. I cannot conclude this note without expressing how much we were struck on arrival here from the front by the excellent arrangements and order so prominent in this hospital, and it must have been a most welcome change for the wounded after all the discomforts inseparable from the journey down from the front by boat to have been able to occupy the airy and comfortable wards fitted with all the comforts of a hospital in Cairo.

Hospital on Line of Communication, Abadia, Soudan,
Sept. 11th.

[1] We announce in another column that the *Mayflower* left Assouan for Cairo on Sept. 15th with 28 wounded and 24 sick.—ED. L.

BRITISH ASSOCIATION.—At the concluding meeting of the British Association, held at Bristol on Sept. 14th, Professor Schäfer reported that the grants appropriated to scientific societies amounted to £1485, and added that this unusually large amount was able to be given owing to the great success of the Bristol meeting.

THE LANCET.

LONDON: SATURDAY, OCTOBER 1, 1898.

IN studying the life of PASTEUR on one can fail to be struck with the practical bearing of all his investigations and with the eagerness with which he set himself to improve the industries of the districts in which he happened to be placed. His brilliant investigations upon the diseases of silkworms, upon vinegar, upon the diseases of wine and beer, and upon sewage fermentation are matters of history. He was essentially a patriot and a citizen who delighted to place his knowledge at the service of his country and of his town. Yet we are quite familiar in this country with the criticism that our centres of learning, our universities, are not in touch with the industries of the community in the midst of which they exist. We receive an impression that the teaching of anything technical does not appertain to a university. What has been the result of this old university idea? It has been that the manufacturing chemist has established a laboratory in his own works, a well-equipped research laboratory, the investigations in which are turned to his own profit. The same may be said of the brewing industries. If the seats of learning have not appreciated "technical" education the manufacturers have done so in numerous instances. Instead of the great cities in this country possessing universities of their own in which the student could be trained for a classical, a medical, a legal, a veterinary, or a commercial career, or be thoroughly equipped as a chemist, a brewer, an agriculturalist or a commercial man, we find too often in these cities an apology for a seat of learning in which, perhaps, the only flourishing section is medicine, the other subjects requisite to the life of the citizen being neglected and the great manufacturer of the district in consequence being driven to establish a laboratory exclusively for his own use. The changes which are, however, taking place in Liverpool and in Birmingham, to be probably followed by Bristol and Sheffield, indicate a commencing reaction against the old university system and a determination to found centres of learning more in touch with present-day needs, where research and learning may be prosecuted in a scientific manner and in well-equipped laboratories, whether the subject is butter-making or the study of tropical diseases.

What better indication could we have of the determination to apply scientific methods to commerce than the interesting meeting which was held at Lord VERNON'S country seat on Sept. 15th and reported in THE LANCET of Sept. 17th? It was a gathering of scientific men to see the establishment of a laboratory in connexion with a dairy—a laboratory in which the quality of the milk could be tested regularly, chemically, and biologically, and in which researches on the bacteria present in milk could be conducted. If the chemist or the brewer has found it profitable to establish his own laboratory surely it is a step forward on Lord VERNON'S part and one which is likely to yield much good fruit and have far-reaching effects if the noble lord proceeds on similar lines. It is perfectly certain that perishable food-stuffs, whether dairy products, meat, or jams, when dealt with in large quantities, would yield far greater profits if those who had to deal with them possessed a scientific knowledge. This becomes strikingly apparent if we consider the amount of good food assuredly lost through want of knowledge of biological laws: the jam manufacturer loses half his preserves, a cargo of meat is spoiled, firkins of butter turn out rancid, the milk becomes quickly sour, and so on. Lord VERNON'S effort deserves the greatest praise, although it might cause our Danish friends or American cousins to smile, so used are they to what we must treat as a radical departure; and we hope his example will be followed. His cows are hygienically housed, they are all tested with tuberculin, and the milk is carefully centrifugalised. A further feature is the placing upon the market of sterilised milk. This is most certainly a great desideratum as far as our experience goes. Sterilised milk, even when three or four weeks old, tastes very like fresh milk, and we cannot help thinking that, after all, boiled sterilised milk bears the same relationship to fresh milk as, say, roast beef to raw beef. There is no doubt the raw beef has its value, but no one denies the nutritive use of roast beef, and it is probably similarly the case with boiled milk.

To return to the university question, Lord VERNON'S experiment shows the necessity for better and more scientific agricultural departments than at present exist in the country and that it is incumbent upon the teaching colleges in agricultural districts to make provision for laboratory training. We hope the lesson will not be lost upon our teaching bodies and that they will not allow the matter to be left to individual enterprise. Municipal bodies have become quite alive to the fact that the questions of milk-supply and of water-supply are exceedingly important and developments in technical knowledge are now sure to follow. Let the universities be ready to lead. Liverpool and Manchester have their bacteriological as well as their chemical analyst and other large cities will no doubt follow suit. We deal with the present position of London in relation to a public bacteriological laboratory in another article. That official supervision of the milk-supply is necessary is shown by the fact that from 2 per cent. to 5 per cent. is the frequent average of tuberculous milks. The tuberculous milk is more frequently milk brought into the city from the country and is obtained from cows in shippons which cannot be inspected by the city authorities. Lord VERNON'S example is therefore of great service to other producers and helps further to protect the consumers in the large towns.

IN a communication from a correspondent published in THE LANCET of Sept. 24th, p. 819, a most important question is raised — the possibility of making arrangements for the appointment of an expert or experts who would be available to carry on examinations of material from suspected cases of infectious disease specially with

Digitized by Google

a view to afford aid in diagnosis. The necessity for such arrangements being made in connexion with the maintenance of the health of a city like London has long been demonstrated, but the best method of carrying them out has still to be carefully considered. The value of well-equipped and well-manned laboratories has now been most fully recognised in New York, where Dr. SHERMAN BIGGS, the director, has at his command a staff of scientific workers who might well bring credit to any institution. He also has such a laboratory and clerical staff that he is enabled to leave his scientific workers free to carry on their special duties and at the same time to keep record of, and make public in a readily accessible form, the results of the investigations carried on. He is enabled to do all this because he has a free hand and is well supplied with the sinews of war—a sum of nearly £20,000 passing annually into, and out of, the coffers of the laboratory department. How much can be done on a small scale has already been demonstrated in this country, where the Clinical Research Association has afforded very great assistance to private practitioners, whilst to vestry and district boards and the Metropolitan Asylums Board the British Institute of Preventive Medicine and the laboratories of the Royal Colleges of Physicians of London and Surgeons of England have done work the value of which can at present be very inadequately estimated. In Manchester Professor DELÉPINE, working in conjunction with Dr. NIVEN, has organised in the Owens College a system of laboratory investigation which promises to effect a complete transformation in the character of the work of the Health Department in the Manchester district. Liverpool in the same way now utilises the services of Professor BOYCE and his staff, with the result that the medical officer of health, Dr. HOPE, has always at his disposal the best bacteriological and pathological advice to be obtained. In this matter Manchester and Liverpool have followed the lead of such cities as Paris, Berlin, and Lille, where there appears to be a definite arrangement between the municipal authorities and the great pathological and bacteriological institutes by which the former obtain the benefit of the use of the laboratories and workers in the institutes and the latter receive substantial subsidies through the aid of which they are enabled to become vastly more efficient than they could otherwise hope to be.

It would be well that all these various plans should be carefully considered before any step is taken or any scheme put forward which is not based, first, on the needs of the city as a whole, and second, on the feasibility of its adoption and carrying out. The first point at present requires little consideration. The work to be undertaken is already of such magnitude, both as to quantity and character, that search for it is absolutely unnecessary. The second point, however, is one which requires more careful consideration and it is well that it should be taken up at once, as no more favourable opportunity could have arisen.

One important aspect of the matter to be carefully considered is that there are in London at the present time two large institutions, built and supported at considerable cost, in which, were funds at the disposal of the managers, the whole work of a central department could be carried out at an earlier date, more efficiently, and at probably half the cost to the ratepayers, than were an entirely new laboratory to be erected. It is possible that one or both of these institutions may be included in any complete scheme which is adopted by the London University Commissioners, so that ere long they would be in touch with a body on which the London County Council will, if a forecast may be made, be represented. These two institutions—the laboratories of the Royal Colleges of Physicians of London and Surgeons of England on the Victoria Embankment and the British Institute of Preventive Medicine at Chelsea—are, we believe, both well equipped for the carrying on of such work as that referred to in our correspondent's communication and, so far at least as the funds at their disposal have enabled them, have for some years been engaged in carrying on some of the work elsewhere undertaken by public laboratories. At present the only obstacle to the carrying out of the whole programme outlined in our columns is that there are not sufficient funds at the disposal of the managing authorities for the payment of such a staff as would be required, which could only be collected slowly and educated as found necessary. At both places there is already the nucleus of such a staff, a nucleus which could readily be added to as occasion might demand.

In a movement of this kind it would be a grave mistake if the main aim of the foundation of such a central department were lost sight of and money were frittered away on any scheme which might in time become obsolete. It should be understood from the outset that no laboratory in which mere diagnostic work is undertaken could have the slightest chance of permanently fulfilling the functions required of it. That being the case, it is obvious that the staff must be so large that those engaged in doing the diagnostic and other routine work should have time and opportunity for carrying on original scientific work by means of which they may not only keep abreast of what is going on around them, but have the opportunity of utilising the wealth of material which would be focussed in such a department and of giving forth the results of their investigations for public use. Without the stimulus of original investigation there will always be a tendency for anyone carrying out merely diagnostic work to fall into routine methods and to become a mere drudge whose assistance, though sufficient for the immediate end in view, must inevitably become less and less efficient as time goes on and new discoveries are made. It is an almost universal experience that routine scientific work soon loses its character unless the stimulus of one of two occupations be constantly applied. The first of these, teaching, the delight of some men, is little more than boredom to others, whose bent is rather towards original investigation, but a combination of men who, in addition to conducting teaching or research work, should be called upon to supervise diagnostic work and investigate complicated pathological and bacteriological problems would result in the carrying on of an ideal work in this great city of ours.

It must be borne in mind that the work of a laboratory of this kind would in the course of a few years cover an enormously greater extent of ground than it at present does and that the tendency would be for more and more problems to be brought there for examination and solution, whilst the amount of routine work would probably increase

Digitized by Google

at an even greater rate than that of a more complicated nature. Consequently any plan at present adopted would have to be of such a plastic and elastic form that under proper guidance it might be moulded or expanded to meet all requirements as they arise. Matters stand, then, much in the following position. There is need for a great central department for the investigation of pathological and bacteriological problems and for assisting medical men in diagnosis by microscopical and cultural methods. Such a department must obviously be in addition to smaller local laboratories, where much of the routine work which requires little special experience may be carried on by men who wish to acquire facility in any diagnostic methods before they commence their final clinical work, in order that such methods may gradually become part of their clinical "outfit." This department must be placed on such foundations and constructed on such a plan that there shall be ample room for later expansion.

The basis of such a department already exists in the buildings and "skeleton" staffs of the laboratories of the Royal Colleges of Physicians of London and Surgeons of England and the British (or Jenner) Institute of Preventive Medicine, which between them could certainly supply all the laboratory room necessary for carrying on (*a*) diagnostic, (*b*) experimental, and (*c*) teaching of training work requisite for the ultimate success of a central department. There would be the great advantage that the work could be commenced at a very early date after the necessary arrangements as to control, management, staffing, &c., had been made. The initial or capital outlay might be looked upon as likely to be very small indeed, whilst an annual outlay of a comparatively small sum would in the first instance ensure such additions to the present staffs as would be ample for existing needs, and only as the needs became greater and the system developed on natural and demonstrably useful lines would greater outlay be called for.

One of the great obstacles to the carrying on of systematic investigation is the difficulty which exists in obtaining sufficient funds for the payment of capable workers. The result is that splendidly equipped laboratories have to depend in great measure for their utilisation on what may be called volunteer workers, men who have all the devotion and enthusiasm necessary to become good workers and who carry to successful conclusion many most valuable investigations, but who are hampered in so doing by the fact that having a living to earn they cannot devote their whole time and undivided energy to the kind of work involved in these researches. Under some central and controlled scheme, taking in the two large laboratories above mentioned and others as might be deemed necessary, this obstacle could be easily and finally removed. Men could give half their time to carrying out routine work of examination and diagnosis and would be able with the pay received for that work to devote the remainder of their time to teaching or to scientific investigation or both, by means of which they would keep themselves well up to date and thoroughly efficient.

The present seems to be an opportunity not to be lightly thrown aside, and it is to be hoped that the example set by Edinburgh, Manchester, and Liverpool will not only be followed but improved upon, and that the facilities for carrying on work already in existence may be utilised in a greatly extended form. An annual subsidy under certain control and conditions, divided by arrangement and set apart for the payment of expenses and salaries incurred for the carrying on of diagnostic work, would not only enable such work to be done, but would also increase in a most marked degree the efficiency of the functions for the performance of which these laboratories were originally designed, and all this at a cost which, compared with the equipment and staffing of new laboratories, would at first be little more than nominal to the bodies interested in this new movement. The gain to the health authorities on the one hand and the benefit to science on the other would, we believe, be simply incalculable. London has moved late and slowly in this matter. It is to be hoped that now the movement will be well directed and thoroughly effective.

WE publish in another column the gist of an address by Dr. J. C. MCVAIL, the medical officer of health of Glasgow, which he delivered as President of a Conference of Medical Officers of Health held in Birmingham on Wednesday last in connexion with the annual meeting of the Sanitary Institute. Dr. MCVAIL chose for the opportune subject of his remarks "The Medical Profession and the State: their Relationship, especially with regard to Vaccinal Legislation," and dealt with his theme in the well-informed, lucid, and bright manner which he has accustomed us to expect from him. In addressing an audience of medical officers of health over 1000 of whom have recently testified by signed declaration their conviction that vaccination and revaccination prevent and control small-pox and that small-pox cannot be effectually prevented and controlled without these means it need hardly be said that the speaker was not obliged to waste time in urging the value of the procedure. Nor did he consider himself called upon to criticise in any detail the merits or demerits of the new Vaccination Act. This Act has no mention of revaccination, an omission which must to some extent condemn it in the minds of the authors of the representation affirming the enormous protective value of revaccination. But Dr. MCVAIL judiciously refused to condemn the Act either because of this omission or because of the abolition of the compulsory element. On the contrary, he warned his hearers against making up their minds too speedily as to what the outcome of the new legislation will be, and this, we think, was wise advice. It must be remembered that under the old system vaccination had come to be, as Dr. MCVAIL happily styled it, "a matter of local option," while it is within the knowledge of all medical men that where the feelings of the community went against the treatment no real pressure was brought to bear against the individual who broke the law. The law was to an appreciable extent in abeyance when Mr. CHAPLIN'S Act was passed, for in many districts the boards of guardians to whom the starting of punitive proceedings had been entrusted under the old law declined to take any step. But under the new Act the Local Government Board may be expected to see that the letter of the law is complied with and that parents who desire to avail themselves of their new right to withhold their children from vaccination do so only

Digitized by Google

in accordance with prescribed form. "In fact," says Dr. MCVAIL, "individual option will take the place of local option," and we agree with him in thinking that it would be rash to prophesy that under the new system the vaccination default will be any greater than it was under the old. Certain vulgar inducements to keep children back from vaccination are now wanting, and with the present lack of opportunity to snatch a cheap martyr's crown will come a decrease in the number of persons who resist vaccination unthinkingly and at the expense of their infants' lives for the sake of what they can get out of their pose as the victims of oppression. That most conscientious thinkers will range themselves for the future, as they have done in the past, on the side of medical opinion, is certain; but it is also probable that a large proportion of the community who have hitherto allowed themselves to be led by false prophets will now pause, think, and return to the fold. The absurd statements made recently by "conscientious objectors," on which we comment immediately below, cannot fail to reveal the position of the average anti-vaccinationist as somewhat absurd.

THE conscientious objector has passed from the purview of the Legislature into that of the magistracy, and the rapidity with which he has been hustled from the high court of Parliament into the humbler law courts has caused him to arrive there in a somewhat dishevelled and nondescript condition. So insufficiently, indeed, was he described and labelled before being despatched that there has been some difficulty in recognising him on his arrival, and in various instances the bench, denying his right to use the name which he claims for himself, has sent him away uncertified and dissatisfied. At Lambeth Court he declared his objection to be that vaccination is unnecessary and inefficient; but he added that he would be quite willing to have his child vaccinated if he believed in the efficacy of the operation. The magistrate refused to accept this and told the man to go home and make further inquiry. The same advice was given to a North Londoner who "had heard" that calf lymph sometimes develops consumption. The magistrate here adopted the Socratic method, thus: "Mr. MEAD: What do you do when you are ill? Applicant: Go to a doctor.—Mr. MEAD: Why do not you cure yourself? Because the doctor is skilled in his profession.—Mr. MEAD: If you have confidence in the medical man in one case, why not in another? You had better go away and reconsider the matter." Another applicant averred that he himself had been vaccinated half-a-dozen times, but only once successfully, and though he would not allege that this had done him any harm he complained, "It put me to a lot of trouble." This man also was sent away empty-handed.

Sometimes the objections have been of a religious nature. One man argued at Greenwich "that the child is made in the image and likeness of GOD" and that "it was not meant that GOD'S skin should be cut about." An amateur theologian of Birmingham declared that "if it were necessary for man to be inoculated by beast" the Creator would have done it before the child was born. The magistrate's clerk held that this man might as well expect the Creator to provide him with pocket-handkerchiefs. In the end, however, the required exemption was granted. These objectors belong to the class who opposed small-pox inoculation in Lady MONTAGU'S time on the ground that it tended to "banish Providence out of the world," and to the early opponents of vaccination who held that JENNER'S scheme was "perhaps a daring violation of our holy religion" and that "it was impious and profane to wrest out of the hands of the Almighty the Divine dispensations of Providence," small-pox itself being "a merciful provision on the part of Providence to lessen the burthen of a poor man's family."

At Hampstead the guardians' clerk was himself an objector and here the magistrate—Sir HENRY HARBEN—felt so much difficulty that instead of certifying "We are satisfied that he has such conscientious belief," all the length he would go was "We have no reason to doubt." The applicant then betook himself to the guardians whose clerk he is and requested them to obtain at the public cost counsel's opinion as to the validity of the certificate. His request was not granted and, according to the newspaper reports, the chairman remarked that "if anyone wanted encouragement for a series of fads in the parish he had only to point to the action of their clerk." Perhaps the most reasonable of the objectors was one who declared before Mr. SHEIL, "Well, sir, I lost one child, I thoroughly believe, through vaccination, and I do not wish to run the risk with a second child, not a very strong baby." Mistaken as this parent in all probability was, yet his declaration might well be classed as conscientious. In some other cases a vague general statement that vaccination has a prejudicial effect upon health was accepted as sufficient. There is no doubt that magistrates have been placed in considerable difficulty by the want of definition of the phrase "conscientious objection" in the new Act and by the duty which is laid upon them of "satisfying" themselves that there is conscientious objection. One point which seems to be agreed on by the London magistrates is that testimony upon oath is unnecessary. That is surely unfortunate, as a declaration relating to the health and life of a human being should be made with all the seriousness and solemnity which the forms of the law can provide. The fee of a shilling which is to be charged for a certificate will, we expect, be denounced as the indirect imposition of a fine, but it should be useful in so far as it may act as a deterrent to some who might otherwise be objectors, and if there is anything in this view it indicates how small a part conscience may play in the matter.

In the absence of definition it is likely that magistrates will attach more and more importance to the fact that a man is willing to lose half a day's work in order to get rid of the need for procuring the vaccination of his child. In that case a decision by Mr. MEAD at the Thames court is of very considerable practical importance. The mother of the child applied for a certificate of exemption. Mr. MEAD asked if she had a husband and the reply was, "Yes; but he can't lose a day's work to come here. It makes no difference whether he or I come," to which Mr. MEAD answered, "Yes, it does. If I give a certificate it must be to the responsible guardian of the child." This is as it ought to be, and we trust that every bench of

Digitized by Google

magistrates will follow Mr. MEAD'S clear-headed example. It is, of course, much too early to attempt to form any definite opinion as to the effects of the new law or the extent to which recourse will be had to the conscience clause. The action of those boards of guardians which, owing to the want of a conscience clause, have of late refused to administer the Act will be watched with special interest, but some time must elapse before the boards all over the country can be expected to elaborate the details of their procedure under the new system.

Annotations.

"Ne quid nimis."

SOME POINTS IN THE LONDON WATER-SUPPLY.

IT is possible that the present distress occasioned in the North-east areas of the metropolis by the unprecedented drought will do more towards hastening a better state of things in regard to London's future water-supply, its quality, quantity, and administration, than any other event could possibly have done. This is not the first time that the portion of the population of London which is now suffering from a scanty water-supply has been placed in the trying situation in which it finds itself. The Lee as a source of supply has failed under conditions which it must be admitted are exceptional, but it has failed before under less trying circumstances and no margin can be allowed on the question of providing life's first necessity. It remains to be considered whether, taking the sources of supply as a whole, the London watershed can be regarded under all conditions as adequate to the needs of a rapidly growing population. It is said that the other large water companies are not feeling so far any serious effects as a result of the drought, for some of them have enough water to spare, it appears, to relieve the shortage of the East London Waterworks Company. It seems clear, however, that up to the time of the present distress there was practically no provision made by which the mains of one company could be connected with those of another. As will be seen by reference to our Special Commissioner's articles, the East London Waterworks Company has two connexions with the mains of the Grand Junction Company, which company has also a connexion with the Southwark and Vauxhall Company. Recently a main was completed which joined the Kent system with the East London system and further, a junction has been made with the Southwark and Vauxhall Company through the Tower Bridge subway, which together will yield an auxiliary supply of 6,250,000 gallons per day. Other direct means of adding to the supply do not appear feasible, but the West Middlesex Company may join their mains with those of the Grand Junction Company, which will maintain the supply thus indirectly to the East London Company. This, according to Mr. Chaplin, will give an additional million gallons of water, but the connexion cannot be effected for some weeks yet to come. Thus it is estimated that a deficiency of 15 millions of gallons will be partly met by some 12 millions of gallons from these supplementary sources. Mr. Chaplin's comprehensive reply to a deputation representing the districts supplied by the East London Company on Sept. 24th may be taken almost as a declaration of policy, affording, we think, a glimpse at any rate of the attitude which the Government may be expected to adopt in relation to the entire question. He seemed to foreshadow the creation of a central administrative body. He was not content to restrict himself to the water famine in the East-end, for he touched also with no uncertain sound upon the greater questions of new administration, of municipal purchase, and of the scope of the Royal Commission presided over by Lord Llandaff and the probability of the Government dealing promptly and decisively with the matter. It will be admitted that Mr. Chaplin's review of the situation in the East-end of London was perfectly correct. The East London water-supply, he said, had failed on account of an abnormally low rainfall. In other words, the Lee is not equal to the demands of the two great water companies, and the New River Company drawing on the upper reaches of the river has so depleted it as to leave little to flow to the intakes of the East London Company in the lower reaches. The New River Company also derives a large supply of water from wells, upon which, however, the drought is having a very serious effect, so that it may not be convenient to them to sell water to another company for an indefinite period. The minor wells in the neighbourhood have practically disappeared as a source of local supply. This fact introduces a very important element into the question of London water-supply. Those living in the area immediately outside London not unreasonably contend that they should have a voice in the matter relative to the management of the supply, which could not be the case if the new administrative body were composed exclusively of representatives of the London County Council. The deputation urged upon Mr. Chaplin to convene an autumn session of Parliament in order to give the subject full discussion while the present situation was fresh in everybody's mind, but Mr. Chaplin expressed the opinion that an autumn session would be futile, while it should be remembered that the Government was waiting for the results of a practical Commission of Inquiry, that being now held by Lord Llandaff. Putting aside the great questions of policy in the matter of purchase and control it is obvious, we think, that the first step which legislation must take will be the establishment of a system by which the mains of all the different water companies in London could be instantly connected in the event of emergency at any one point. This cannot be a matter involving any large scheme of engineering, and if what has already been done had been done sooner, it would have saved the East-end of London from much hardship and distress. Upon this very important point, to which Mr. Chaplin so emphatically referred, the recent inquiry undertaken by ourselves as to the machinery, plant, and distributing services of the London water companies[1] should afford information of a very pertinent character.

SCHOOL BOARDS AND THEIR MEDICAL OFFICERS.

THE Halifax School Board had a meeting on Sept. 19th when the following report of the committee regarding the duties and remuneration of the medical officer was presented:—

"Reporting as to the duties of the medical officer to be appointed by the board the board in committee recommended that they should be as follows:—'(1) To examine when required by the board or the school attendance committee children who are said to be physically unfit to attend school and all children whom it is proposed to send to the "special" classes, and to make out certificates; (2) to examine probationers and candidates for pupil teachership, also pupil teachers at the end of the second year of their apprenticeship, and to make out the certificates required by the Education Department; (3) to visit and report in writing when required by the board or any of its standing committees on any employé who is absent from

duty on account of illness; (4) to examine candidates for employment under the board or employés when required by the board or any of its standing committees, and to make out certificates; (5) to examine and report upon cases of blind and deaf children when required and to make out certificates; (6) to visit each department not less than once every three months, or oftener if required, and report in writing on any sanitary defect of the premises to which his attention may be called and on the general health of the scholars; (7) at such periodical visits to examine and test the eyesight, hearing, or other physical condition of any scholar to whom attention may be called by the head teacher.' It was further agreed, 'That the remuneration for the foregoing duties be 75 guineas per annum, the engagement with the board to be for a period of one year.'"

The Rev. Father Quinlan moved, and Mr. Robertshaw seconded, the adoption of these proposals. Mr. Bates moved as an amendment that the salary should only be 50 guineas, and Mr. Braithwaite seconded. The Rev. Father Quinlan said that he did not consider the appointment of medical officer necessary. If, however, they were going to have one he personally would give him a much bigger salary than 75 guineas. Eventually 5 members voted for the motion and 5 for the amendment and the chairman gave his casting vote for the amendment. Another amendment was then moved to refer the matter back to the next meeting of the board and this was carried. Considering the amount of duties the medical officer may be required to do 75 guineas is none too much; in fact, we consider it quite inadequate. The sum proposed is somewhat less than the remuneration of a butler, but, of course, the care of other people's children is a less onerous and responsible office than the care of another person's plate and wine. The population of Halifax is in round numbers 90,000, so we suppose there are about some 9000 children in its Board schools, judging from the case of London, which has 500,000 children out of a population of 5,000,000. Besides looking after the children the medical officer will also have to inspect sundry pupil teachers. If the Halifax board is going to pay at all let it give a decent salary; otherwise let it frankly ask candidates to come forward for the honour and glory of the post.
